 In the replicator dynamics, one mathematically models the evolution of strategies by considering a population that is initially populated, in some arbitrary proportion, by at least two different strategies. In this model, it is assumed that any arbitrary pair of individuals is equally likely to interact. When they do, each will receive a payoff that is defined by the underlying game. Thus, if both the proportion of strategies in the population and the structure of the game are known, then the expected payoff that each strategy will receive in an interaction can be calculated. In the replicator dynamics, it is assumed that if a particular strategy has an expected payoff that is less than the average payoff in the population, the number of individuals using that strategy will gradually diminish. Conversely, if a particular strategy has a higher than average expected payoff, then the number of individuals using that strategy will gradually increase. This behavior is usually represented by a system of differential equations, which is solved to yield a description of the state of the population at any time in its evolution.

 In the replicator dynamics, it is often the case that there is some proportion of strategies at which each strategy has the same expected payoff in the population. If this is the case, then the replicator-dynamics model implies that the representation of each strategy in the population will not change. Similarly, it is possible that one strategy will come to predominate in the population, while the other strategies gradually disappear.

 Evolutionary games are most explanatory when such stable configurations of strategies exist. Typically, the explanatory strategy is to note that, unless there are powerful external influences on the population, one is most likely to observe a real-world population in a stable state, or approaching a stable state. In this way, an evolutionary model is capable of yielding specific predictions, without the use of the rationality assumptions of rational choice theory.

 It is possible, of course, to derive different dynamical models that are best interpreted as models of learning processes, or that employ different assumptions. The best known of these is the “aspiration-imitation” model, which specifically represents the dynamic as a learning process that has various parameters that can be adjusted for the specific model.

 Although the term evolutionary game is often used in a way that makes it synonymous with the replicator dynamics, it is more accurate to think of evolutionary game theory as a general framework that contains a large variety of different models. These models vary, not only in the specific parameters that define their behavior, but in more dramatic ways as well. The learning process, the cognitive sophistication of the agents, the size of the population, and the speed with which the population evolves are just some of the variables that may be taken into account in an evolutionary game (see Samuelson 1997 for an excellent survey). Evolutionary game theory is thus a flexible tool, and its study is rewarded by the large number of applications to which it can be put.

EVOlUTIONARY PSYCHOLOGY

Evolutionary psychology proposes a set of evolved psychological mechanisms to account for much, if not all, human behavior. The research program is one among many in the social sciences that argues for the relevance of evolutionary biology in understanding human behavior. Evolutionary psychologists argue that explanations in psychology, and social science in general, are inadequate to the extent that they ignore human evolution. Evolutionary psychologists aim to unify psychology and other social sciences and improve their explanatory capabilities. Evolutionary psychology is related to human sociobiology but evolutionary psychologists present an important criticism of human sociobiology: sociobiologists ignore the psychological mechanisms that produce human behavior. To this extent, evolutionary psychology is seen as an advance over human sociobiology because it is consistent with cognitivism in psychology. Evolutionary psychologists share cognitive psychologists’ view that humans’ internal psychological mechanisms are contentful representational states, sometimes referring to these mechanisms as “Darwinian algorithms.” Behavioral psychologists argue that humans have no content internal representational states, which is in stark contrast to the cognitive perspective.

Evolutionary psychologists’ key contribution to the social sciences is the idea that the human mind consists of many separate psychological mechanisms, each of which was formed by natural selection. An analogy with organs illustrates this key insight: Many human organs are adaptations—direct descendents of organs that helped our ancestors survive and reproduce. Keeping with the analogy, these researchers point out that although all psychological mechanisms are adaptations, they need not all be currently adaptive, just as humans’ appendices are adaptations but are not currently adaptive. Similar to human organs, the relevant adapted mental mechanisms are distinct and evolved independently of one another; they are modular.

A large number of experimental projects gave weight to evolutionary psychologists’ theoretical claims. Psychologist David Buss’s 1990 study of human mate selection found large numbers of cross-cultural commonalities in mate choices. These commonalities were attributed to various underlying psychological adaptations that drive human mate choices. Leda Cosmides’s work during the 1980s in the psychology of reasoning presented a new way of dealing with a type of reasoning puzzle called Wason selection tasks. Wason selection tasks are presented in the context of psychological experimentation on human reasoning. In the earliest of these, test subjects were presented with abstract tasks that could be solved correctly by use of deductive logic. Most subjects fail to deal with such tasks correctly and subsequent researchers introduced versions of the tasks with the same logical structure but presented in a context that subjects understood. These versions of the task produced a huge improvement in performance. Much of the psychology of reasoning has focused on explaining this performance difference. Cosmides proposed that performance goes up on Wason selection tasks when they are construed in terms of social exchange because humans are deploying an evolved psychological mechanism for social exchange to carry out the selection task.

Other experimental results reported by evolutionary psychologists include controversial work on rape and murder, as well as work on many aspects of reasoning, moral judgment, sexual attractiveness, parenting, taste, aggression, cooperation, and mental health. The Handbook of Evolutionary Psychology details the theoretical underpinnings of the field and introduces many of the key results from empirical work. This book develops and advances upon the program announced in an earlier work, The Adapted Mind.

Evolutionary psychology is an extremely productive research program. Evolutionary psychologists produce a large body of both academic and popular work. This work simultaneously advances a research program and provides responses to the various critics of the program. The first broad type of criticism is mounted by social scientists who view evolutionary psychology as a kind of biological determinism. Evolutionary psychologists reply that neither biological determinism nor cultural determinism is a viable explanatory strategy in the social sciences if pursued exclusively. Critics respond that the reductionist goals of evolutionary psychology imply that they are not as ecumenical as their response would indicate.

There are two other types of criticism of evolutionary psychology. One critique comes from researchers in other biologically based social sciences, such as evolutionary anthropology, who argue that evolutionary psychologists’ presuppositions about human evolution are mistaken and that their hypotheses are not subjected to the testing procedure that analogous hypotheses undergo in evolutionary biology. This debate is about how to develop and test hypotheses about adaptation. Much of this discussion has centered on the issue of whether to test for adaptive behavior or to attempt to ascertain whether a certain
behavior is the result of a particular adaptation. Evolutionary anthropologists adopt their methodology from behavioral ecologists. This approach emphasizes producing models to test the extent that animal or human behavior is adaptive. Evolutionary psychologists argue that ascertaining whether or not a trait is currently adaptive for the animal or human is not the same as ascertaining whether the trait is an adaptation or whether the behavior results from an adaptation. Evolutionary anthropologists counter the hypotheses that the extent to which behavior is adaptive can be rigorously tested and is relevant with the question of whether or not behavior is an adaptation or results from an adaptation.

The other type of criticism comes from philosophers of science, who place almost every aspect of the research program under critical scrutiny. Such critics reject both the theoretical tenets of the program, such as the modularity assumption, and the viability of experimental results.

Many philosophers of science, including philosopher of biology David Buller, have argued that evolutionary psychologists are mistaken in claiming that human minds are massively modular. Such arguments are derived from work in biology and from alternate views about human mental architecture defended in the cognitive sciences and neurosciences. Philosophers also argue that evolutionary psychologists are committed to an untenable version of adaptationism. Buller’s version of this latter criticism is developed along similar lines to the criticisms presented by evolutionary anthropologists. One idea here is that not all adaptationist hypotheses should be considered equal and only those that are susceptible to rigorous empirical test should be pursued. Philosophers present another version of this point arguing that evolutionary psychologists’ version of adaptationism is not consistent with evolutionary biologists’ adaptationism and is therefore suspect. It is important to emphasize that critics from evolutionary anthropology and philosophy of science share evolutionary psychologists’ view that evolutionary biology is crucial in the overall project of understanding human behavior. The critics disagree with evolutionary psychologists about the way in which biology should be brought to bear in the study of human behavior.

There is broad agreement among some social scientists that much of human behavior will only satisfactorily be accounted for by using biological based explanatory models. Such agreement does not commit these researchers to the view that evolutionary psychologists have isolated the one correct way in which biology should be brought into social science. There is still a great deal of theoretical and experimental work to be done at the intersection of biology and the social sciences. This is an exciting growth area to which evolutionary psychology makes one prominent contribution.

**EXCESS DEMAND**

Intuitively speaking, *excess demand* (ED) refers to a condition where, in a neoclassical framework without externalities, demand and supply do not match. In particular, there is ED when, in a certain market and for a given demand-and-supply curve, a certain price level $p'$ generates insufficient domestic production to offset the corresponding domestic demand. Analytically speaking, excess demand can be considered from both a microeconomic and macroeconomic point of view. In microeconomics, ED can be analyzed in a partial or in a general equilibrium framework.

The easiest way to illustrate ED is to start from a partial equilibrium analysis. Let’s assume that in a certain market the (inverse) demand-and-supply curves are represented by the following linear functions:

\[
\text{Demand (D): } p = a - bq \\
\text{Supply (S): } p = c + dq
\]
where \( p \) and \( q \) represent price and quantity respectively, and \( a, b, c, \) and \( d \) are real positive numbers. Clearly, the equilibrium occurs when the two schedules intersect. Therefore, we get:

\[
\begin{align*}
q^* &= \frac{a - c}{b + d} \\
p^* &= \frac{ad + bc}{b + d}
\end{align*}
\]

In practice, when the price level is exactly \( p^* \), consumers demand the precise quantity that producers want to supply—that is, \( q^* \). Hence, ED is zero.

Let's now suppose that for whatever reason the price is below its optimal value, that is, \( p' < p^* \). When this happens, as seen in Figure 1, consumers demand \( q^d \), but producers want to supply \( q^s \) only, with \( q^s < q^d \). Consequently, ED may be defined as:

\[
ED = q^d - q^s = \frac{ad - bc}{b + d} - \frac{b - c}{bc} p'
\]

Note that for a given value of \( a, b, c, \) and \( d \), ED is increasing when \( p' \) is getting smaller, while, needless to say, when \( p' = p^* \), ED is zero.

In a closed competitive economy, ED is an unstable equilibrium. In fact, since consumers cannot buy the precise amount they desire at \( p' \), some of them are willing to offer a higher price. (Note that if producers supply \( q_s \) only, consumers might be willing to pay up to \( p^* \), with \( p^* > p' \); see Figure 1.) However, when consumers start offering a higher price, producers have an incentive to increase their supply. In this way, the lack of balance is reduced; when the price is \( p^* \), demand equals supply, and eventually ED becomes zero.

In terms of social welfare—that is, in terms of consumer and producer surplus—when there is ED, one cannot draw any definitive conclusions for the economy as a whole, or for consumers and producers. If international commerce is allowed, if the goods are tradable, if there are no trade barriers, and if the economy is small—that is, domestic demand for foreign production does not affect international prices—consumers could fill up ED with imports. In this case, consumers would gain, while producers would be worse off. However, the economy as a whole would be better off, because gains would overcome losses.

In a general equilibrium framework, ED in a single market would imply that there must be a symmetric excess supply in other market(s). The simplest way to demonstrate this is to use the Edgeworth box. Let's assume that in the economy there are only two goods, \( x \) and \( y \), with \( p_x \) and \( p_y \) the price of \( x \) and \( y \) respectively. If the optimal consumption bundle—\( x^d \) and \( y^d \)—does not coincide with the production/endowment of the economy—\( x' \) and \( y' \)—then the value of the ED of \( x \), \( p_x(x^d - x') \), must be equal to the value of excess supply of \( y \), \( p_y(y' - y^d) \), or vice versa.

Finally, in macroeconomics, ED indicates a condition where the aggregate demand (AD) exceeds the aggregate supply (AS). That is a condition that potentially stimulates both output and prices to rise. However, once full employment is reached, excess AD will only result in rising prices. In this case in fact, the increase of the price level \( P \), implies that the real demand shifts back, and the economy returns to full employment equilibrium again.

**SEE ALSO** Excess Supply; Welfare Analysis
**EXCESS SUPPLY**

In simple terms, *excess supply* means that there is a surplus of unsold goods in a market. Technically speaking, excess supply refers to a situation in which the quantity supplied of a good or service exceeds the quantity demanded for that good or service.

A graph may be helpful in understanding this concept. In the figure below, price (P) is plotted on the vertical axis and quantity (Q) is plotted on the horizontal axis. The curve labeled “supply” shows a positive relationship between the price and the quantity supplied. In other words, if the price goes up, firms are willing and able to produce more of the good. The curve labeled “demand” shows a negative or inverse relationship between price and the quantity demanded: If the price goes down, consumers are willing and able to buy more. The price labeled “P_e” equates the quantity supplied and the quantity demanded; there is no excess supply in this market. At the price labeled “P_f,” the quantity supplied (Q_s) exceeds the quantity demanded (Q_d), and thus there is a surplus or excess supply in amount Q_s – Q_d.

According to economic theory, if prices are sufficiently flexible, then excess supply should not persist in the long run. Faced with excess supply, firms will simply cut their prices in order to sell any unwanted inventory. However, government price controls can result in persistent excess supply. According to standard economic theory, a minimum wage may result in excess supply. If the minimum wage is set above the equilibrium wage (labeled “P_e” in the figure), the result is excess supply in the labor market or unemployment. If, however, the minimum wage is set below P_e, the minimum wage will have no effect on employment. To be effective, a minimum wage must be set above the equilibrium price.

Of course, governments can and do impose price controls in all sorts of markets. For example, governments often establish minimum prices for crops such as wheat, corn, and so on. To the extent that these price floors are effective, the result is excess supply, and governments find themselves storing large quantities of crops as a result. The European Union and the United States are often accused by developing countries of dumping the resulting surpluses on world markets, depressing the prices of such commodities and, as a result, lowering the incomes of farmers in developing countries.

Do minimum wages cause unemployment? In a seminal paper on the effect of the minimum wage, David Card and Alan B. Krueger (1994) use evidence from the fast-food industry and changes in the federal minimum wage in the United States to gauge the effect of the minimum wage on employment. In contrast to the predictions of the standard model that a minimum wage results in unemployment, they find no evidence that the minimum wages create unemployment. This paper has spawned a substantial literature attempting to replicate these results. Although the evidence is mixed, the general consensus appears to be that modest changes in the minimum wage do not appear to result in dramatic changes in employment, as perhaps economic theory may lead some to conclude.

EXCHANGE, UNEQUAL
SEE Unequal Exchange.

EXCHANGE RATES
An exchange rate represents the price of a national currency valued as a foreign currency. The exchange rate plays a significant role in the economy. Because exchange rate fluctuations influence the whole economy, the exchange rate is a major economic factor for growth, stability, and economic development. In addition, the exchange rate directly influences the unemployment rate and the inflation level, and it is an indicator of external competitiveness (Madura 2003). The exchange rate also affects trade flows and investments, which in turn influence the balance of payments. Generally, the exchange rate is considered the most important price in the economy.

The exchange rate has direct practical importance to those engaged in foreign transactions, whether for trade or investment. It affects the price of imports when expressed in domestic currency, as well as the price of exports when converted into a foreign currency. The exchange rate therefore has a link to inflation. Consequently, the exchange rate is above all a monetary indicator and occupies a central position in monetary policy, where it may serve as a target or an instrument as well as simply an indicator.

The exchange rate system used by a country is called its exchange rate regime. Countries can choose which exchange rate regime to follow, depending on their goals. Countries may either fix or float their exchange rate, but there are a number of other exchange rate systems between these two extremes. There are four main types of exchange rate regimes: freely floating, fixed, pegged (also known as adjustable peg, crawling peg, basket peg, or target zone or band), and managed float. Within these four systems there are modified or intermediate regimes, such as currency board, dollarization, and monetary union regimes. The following entry analyzes each type of exchange rate regime, highlighting advantages and disadvantages.

FREELY FLOATING EXCHANGE RATE
A freely (clean) floating (or flexible) exchange rate regime, where the monetary authorities refuse any intervention in the exchange rate market, is the simplest type of system. The rate is then freely determined by market forces and can fluctuate by any amount at any moment. More precisely, a pure float is an exchange rate that is determined in the market without any intervention. Flexible exchange rates are determined daily in the markets for foreign exchange by the forces of demand and supply, without restrictions imposed by governmental policy on the extent to which rates can change. Supporters of free floating argue that the foreign exchange market is a highly transparent and efficient market because market forces are left unimpeded. Monetary policy is set autonomously, as deemed appropriate in the domestic context, and the exchange rate is allowed to follow whatever path transpires, consistent with monetary policy.

The advantages of a freely floating exchange rate regime are: (1) markets efficiently allocate resources (including financial capital) since there are no capital flow restrictions; (2) changes in the nominal exchange rate carry the bulk of adjustments to foreign and domestic shocks; (3) there are no opportunities for speculators to profit at the expense of the country’s central bank; (4) demand and supply for domestic currency will be balanced in the market; (5) there is no obligation on the part of the central bank to intervene; and (6) the requirement for a country to hold large reserves is eliminated. Moreover, the monetary authority sets monetary policy, but it has no exchange rate policy since the exchange rate is determined by market forces. Thus, the monetary base is determined and in the control of the monetary authority of the country in question. This implies another advantage, which is that no conflicts can arise between monetary policy and the exchange rate; thus, a crisis in the balance of payments cannot occur because market forces automatically rebalance financial flows and avert balance-of-payment crises. In the absence of balance-of-payment reasons for interfering in international trade and payments, and given the autonomy of domestic policy, another benefit of a freely floating exchange rate regime is the exploitation of the economies of international specialization and labor.

Following a freely floating exchange rate system also brings disadvantages. High nominal and real exchange rate volatility may distort resource allocation, as many resources will be devoted to hedging the exposure of exchange rate fluctuations. Furthermore, the future path of the exchange rate will be uncertain, which may create difficulties for businesses in planning and pricing, and the freedom to operate an independent domestic monetary policy may be abused when, for instance, the government, not being compelled to prevent exchange rate depreciation, may be tempted into inflationary budgetary and monetary policies. In addition, there is a chance of overshooting, which will result in the exchange rate settling at a level not warranted by the country’s financial position, perhaps for a considerable period (Aziz and Caramazza 1998; Kenen 2000).
FIXED EXCHANGE RATE

In a fixed exchange rate regime, exchange rates are held constant or allowed to fluctuate within very narrow boundaries, perhaps 1 percent above or below the initial set of rates. When a country chooses to fix its exchange rate, local currency is assigned a par value in terms of gold, another currency, or a basket of currencies. When the exchange rate begins to move too much, the government intervenes with the devaluation or revaluation of its own currency against other currencies in order to maintain the exchange rate within the specified boundaries. In this case, the monetary authority has to defend the fixed parity: Such government intervention can be direct or indirect. Direct intervention requires a change in international reserves. Indirect intervention, in contrast, is affected by influencing the factors that determine exchange rates through increasing or decreasing interest rates or other economic indicators (income, inflation, etc.), a move that does not involve a change in reserves. There are two types of direct intervention. Sterilized direct intervention occurs when the central bank intervenes in the foreign exchange market while making adjustments to avoid a change in money supply; in other words, the central bank transacts simultaneously in foreign exchange markets and treasury securities markets. In nonsterilized direct intervention, the central bank changes the money supply by selling or buying foreign reserves in the foreign exchange markets.

Examples of fixed exchange regimes include the systems established by the Bretton Woods Agreement from 1944 to 1971 and the Euro zone between 1999 and 2002. Fixed but adjustable exchange rate regimes are similar, with the difference that they allow more fluctuation in the exchange rate. In such a regime, the exchange rate is fixed for extended periods or within very narrow margins, but adjustable if there is disequilibrium.

The advantages of a fixed exchange rate regime include: (1) the fixed exchange provides a stable basis for planning and pricing, and helps to increase investment and international trade; (2) it imposes discipline for monetary policy, restraining inflation; (3) it restrains competitive devaluation of the domestic currency, thus contributing to the stability of the world trade system; and (4) it reduces the risk of price fluctuations and lowers the risk premiums imposed on interest rates. The disadvantages of such a regime include the following: (1) governments cannot definitely determine if the chosen fixed exchange rate is optimal or sustainable; (2) a fixed exchange rate regime could be vulnerable to speculative attacks that may damage the monetary stability of the economy or the exchange rate reserves; (3) maintaining a fixed nominal exchange rate carries the risk of an excessive appreciation of the real exchange rate, which results in a loss of competitiveness and, ultimately, to a speculative run on an overvalued currency; (4) economies suffering from real shocks and having adopted a fixed exchange rate face the risk of a further deepening of the downturn; and (5) a fixed exchange rate regime requires the monetary authority to hold more foreign exchange reserves than other exchange rate regimes (Aziz and Caramazza 1998; Kenen 2000).

PEGGED EXCHANGE RATE

Countries operating under a pegged exchange rate regime “peg” their currency’s value to a foreign currency or some unit of account (e.g., gold, the European currency unit, etc.). Hence, while bilateral parity is maintained, the home currency’s value fluctuates against other currencies in line with the anchor country’s currency (Madura 2003, p. 174). There are a variety of different types of pegged regimes defined by Jeffrey Frankel (1999) as intermediate arrangements or “soft pegs.” These include the adjustable peg, crawling peg, basket peg, and target zone or bands. Under adjustable peg systems, the bands are narrow (up to ± 2.25%) and the target rate is adjusted less frequently and by large amounts. Under a crawling peg, the bands are wider and the peg is regularly reset, sometimes weekly, in a series of minidevaluations. Under a basket peg arrangement, the exchange rate is fixed to a weighted basket of currencies that usually reflects the country’s major trade partners. The target zone or band involves setting wide prescribed margins (bands) within which the government intervenes to maintain the exchange rate. Under this type of regime, a country or a group of countries hold their currencies within a predetermined range, and government intervention occurs only when the exchange rate exceeds this range. In this system, market forces determine the exchange rate. If the exchange rate moves above or below the predetermined limits, the government will intervene to move the price of the currency back within the tolerable zone. If the range is sufficiently narrow, the target zone approaches a fixed rate; if it is sufficiently wide, it approaches a freely floating regime.

Some countries favor a pegged exchange rate because it enhances the credibility of the government’s commitment to low inflation. There is a tradeoff between credibility and flexibility. Other advantages of a pegged exchange rate system are: (1) the country can mitigate pressures for domestic price fluctuations and indicate a signal of responsible monetary policy; (2) the country can reduce inflationary expectations and (3) stabilize the prices of imports and exports; (4) the government can devalue its home currency in response to large shocks; and (5) inflation is limited because such an exchange rate regime limits the government’s ability to issue money when there are no foreign exchange reserves. The disadvantages of a pegged exchange rate are: (1) when a nation links its monetary policy to some other nation, monetary
policy and fluctuations in that other nation will create fluctuations in the home nation’s monetary condition; (2) the country’s central bank loses its monetary independence; (3) a peg system may lead to persistent misalignments if inflation is higher compared to the pegged country, causing a situation in which the home currency could be overvalued and uncompetitive; (4) in order for this policy to be credible, additional institutional measures are required; (5) pegged systems are often targets for speculative attacks; (6) such a regime is not sustainable in small countries with huge capital flows leading to a balance-of-payment crisis; and (7) a pegged system is unlikely to be sustainable when there is full capital mobility.

**MANAGED FLOAT EXCHANGE RATE**

In a managed float (or dirty float) exchange rate regime, the monetary authority influences the movements of the exchange rate through active intervention in the foreign market without specifying, or recommitting to, a preannounced path for the exchange rate. Although market conditions determine the exchange rate, this type of exchange rate regime also involves certain less-specified central bank interventions with various objectives. A managed float exchange rate regime belongs with the so-called intermediate methods because it stands between the extremes of perfectly flexible and fixed regimes. It resembles the freely floating exchange rate in the sense that exchange rates can fluctuate on a daily basis and official boundaries do not exist. The difference is that the government can intervene in order to prevent the currency rate from fluctuating too much in a certain direction. Under a managed float, the goal of intervention is to prevent sharp fluctuations in the short run, but intervention does not target any particular rate over the long run. Generally, the central bank intervenes only to smooth fluctuations. Some governments impose bands within which the exchange rate can fluctuate, which is one of the reasons for calling this approach “dirty.”

Unlike the free float approach, the dirty float protects investors against rapid exchange rate fluctuations. It also provides a more stable investment environment, protects the country from the risk of large exchange rate movements, and mixes market-determined exchange rates with a non-rule-based stabilizing intervention by the central bank, which helps avoid potential crises. The dirty float approach has disadvantages in that the government may manipulate the exchange rate for the benefit of its own country at the expense of another currency merely because this exchange rate regime does not offer transparency. In addition, the dirty float system requires cooperation between exchange rate policy and monetary policy that may lead to conflict; the country’s central bank often cannot determine whether a movement in the rate is short term or long term, thus whether an intervention is warranted; there are no definite rules giving credibility to the monetary authorities to intervene; and such a system may not place constraints on monetary and fiscal policy, resulting in a clash with the exchange rate policy.

**OTHER EXCHANGE RATE SYSTEMS**

The **currency board** is a type of fixed regime, but it is more restrictive and also includes a requirement for minimum domestic reserves in foreign currency and a monetary institution that issues notes and coins fully backed by a foreign reserve currency and convertible into the reserve currency at a fixed exchange rate. This institution cannot act as a lender of last resort, does not regulate reserve requirements for commercial banks, only earns seignorage from interest on reserves, and does not engage in forward exchange operations (Hanke 1999, p. 341). The advantage of a currency board system is that it reduces the real exchange rate volatility. There are drawbacks, however, in the country’s loss of an independent monetary policy, and such a system is often a target of speculative attacks and requires very high reserves of foreign currency (Bell 2001).

A country with a **dollarization** regime replaces its own currency with another foreign currency, usually the U.S. dollar. Such an approach may reduce exchange rate volatility, but it poses the drawback that the home monetary policy is dependent on a foreign country’s policy. This approach amounts to a complete replacement of a local currency with a foreign one, which is a step beyond a currency board. Dollarization, a type of unified currency regime, is no guarantee for growth but can provide macroeconomic stability.

A **Monetary union** or a **currency union** occurs when a group of countries use a common currency issued by a common central bank, as do the twelve European countries in the Euro zone. This type of system reduces real exchange rate volatility, but the member countries lose the stabilization tool of an independent monetary policy. Jeffrey Frankel and Andrew Rose (2002, p. 11), analyzing data for more than two hundred countries, determined that by belonging to a currency union a country triples its trade with other union members. Furthermore, the results suggest that for every percentage of increase in a country’s trade relative to its gross domestic product, membership in a currency union raises income per capita by at least 0.33 percent.

In conclusion, different types of exchange rate regimes have various advantages and disadvantages. Governments must determine which system is the most appropriate for a particular country and for the specified time period. No one system exploits all the advantages without any disadvantages, and no system can be applica-
Exchange Value

ble for all countries, which have different goals and political structures in different periods (Frankel 1999).

EXCHANGE VALUE

Exchange value refers to “the power of purchasing other goods which the possession of [an] object conveys” (Smith [1776] 1960, p. 32); in other words, it expresses the relative price of a good in terms of other goods. Although the concept of exchange value has always played an important role in economic thought, the analysis of how it is determined has been the subject of much controversy.

For Adam Smith, David Ricardo, and Karl Marx it was important to distinguish exchange value from use value. Use value was the utility or the value in the use of a commodity, and was seen as necessary but not sufficient for a commodity to have exchange value. This is illustrated by the paradox of value, whereby things that had the greatest use value, such as air and water, had the lowest exchange value compared to (for example) diamonds, which had a low use value but high exchange value.

According to David Ricardo, commodities derive their exchange value from two sources. First, “from their scarcity,” where commodities cannot be reproduced (e.g., rare paintings, coins, pictures, etc.). These commodities are, by their very nature, a very minor part of what is exchanged in any economy. Second, the majority of commodities are produced by “the exertion of human industry: and these commodities have their exchangeable value determined by the quantity of labour embodied in their production” (Ricardo [1817] 1951, p. 12). This labor theory of value, which was present in a more ambiguous form in Adam Smith’s writings, played an important role in the works of both Ricardo and Karl Marx. The relationship between labor values and prices has been a source of much controversy.

In discussing these three economists, it is also important to distinguish between values that are determined in this way, that is, natural values or prices and market prices. Market prices may diverge from their natural values owing to “accidental” or “temporary deviations” (Ricardo [1817] 1951, p. 89). However, competition in the form of capital seeking the most profitable activity will ensure that the deviation is temporary and will establish a long-run tendency toward uniform profit rates through the economy. “The natural price, therefore, is, as it were, the central price, to which the prices of all commodities are continually gravitating” (Smith [1776] 1960, p. 65).

It is important to note that the factors that determine the natural price are different from the factors that bring market price toward natural prices. This is important because it means that the natural prices will not be influenced by the path taken by market prices as they adjust to their natural levels (Kriesler 2003).

For Marx, the essence of a commodity is that it is produced for its exchange value; in other words, it is produced specifically in order to be sold. It is the generalization of commodity production into all spheres of society that he saw as one of the important results of capitalism. According to Marx, exchange value reflects the underlying social relations and “is in reality only an outward form of the social relation between the … producers themselves” (Sweezy 1968, p. 27, emphasis in original). So the market expression of exchange values reflected deeper social relations. This view should be compared with that of John Stuart Mill, for whom exchange value did not arise “from the nature of things,” but was “created by social arrangements” (Mill [1848] 1994, p. 54).

From the 1870s a new version of economics, sometimes referred to as “neoclassical theory,” came into favor,
and has since become the dominant orthodoxy. The essence of this new theory was a subjective theory of value, where exchange value is determined by utility at the margin. In neoclassical economics, the distinction between use value and exchange value is abolished, as exchange value is now determined by use value at the margins, and the distinction between market and natural prices also disappears. In place of the latter is a distinction between short-run and long-run price determination, with both involving the determination of equilibrium values by the same forces—supply and demand. However, as the forces of supply and demand both determine the equilibrium position of prices in the short and long runs, and push the economy to those equilibria if it deviates, the problem of path determinacy arises. As a result, equilibrium exchange values cannot be determined, in neoclassical theory, independent of the adjustment path of the economy.

EXCHANGEABILITY
In constructing statistical models, social scientists are nearly universally required to incorporate residual terms to capture those aspects of a phenomenon that the model under analysis cannot explain. Linear models are a leading case, where a dependent variable \( y \) is assumed to be explained by a vector of observables \( x \) as well as an unobservable residual \( \varepsilon \), via the equation \( y = x \beta + \varepsilon \), \( i = 1, \ldots, I \). Estimation and inference concerning the model parameters comprised by the vector \( \beta \), in turn, requires a researcher to make assumptions about \( \varepsilon \). Examples of assumptions include independence of the residuals across \( I \), and homoskedasticity (constant variance) of the residuals. Such assumptions are employed because they allow one to construct precise inferential statements such as asymptotic distributions under a null hypothesis, but not because they correspond to any substantive social-scientific ideas.

From the social-scientific perspective, one way to think about what it means to specify a model is to place enough structure on the variable of interest, say \( y \), so that, from the perspective of the modeler, the residuals are indistinguishable. In other words, a modeler should have no reason to believe that the probability description of \( \varepsilon \) differs from that of \( \varepsilon \). If the modeler does believe that these residuals differ, then it would seem that the model needs to be reassessed to see whether these differences call into question the purpose of the model.

To understand the import of this claim, suppose that one is attempting to explain the differences in economic growth between Japan and the United States since World War II and is using a model that does not account for differences in the savings rates between the two countries. For the researcher using the model to find it interpretable as reflecting a causal relation, he presumably must believe that Japan’s much higher average rate of saving versus the United States has no bearing on the residuals associated with the two countries. If he believes that this difference in savings rates induces a difference in the probability descriptions of the two residuals, then he needs to determine how the model may be interpreted in this light.

Exchangeability is a mathematical formalization of the idea that random variables are, from the perspective of their probability description, indistinguishable. A sequence of \( I \) random variables \( \varepsilon_i \) is exchangeable if \( \mu(\varepsilon_1, \ldots, \varepsilon_I) = \mu(\varepsilon_{\rho(1)}, \ldots, \varepsilon_{\rho(I)}) \), where \( \rho() \) is an operator that permutes the \( I \) indices. Note that \( I \) may be infinite. The concept of exchangeability originated in the writings of the Italian probabilist Bruno DeFinetti (see DeFinetti 1972 for a wide-ranging statement of his views in English).

Infinite exchangeable sequences have the important property that they may be interpreted as independent and identically distributed (i.i.d.) sequences. This is known as DeFinetti’s theorem. Formally, the theorem says that the probability measure describing any infinite exchangeable
sequence can be written as a mixture of i.i.d. probability measures. Each sample path realization will obey one of the probability measures, so each sample path will behave as an i.i.d. sequence. De Finetti’s theorem thus provides a basis for the i.i.d. assumption: the interchangeability of errors. A proof of De Finetti’s theorem along with many related results may be found in Olav Kallenberg’s work Probabilistic Symmetries and Invariance Principles (2005). De Finetti’s theorem does not apply to finite exchangeable sequences.

To be clear, exchangeability is not necessary for a statistical model to be interpretable as a behavioral structure. Heteroskedastic regression errors (regression errors of varying variance) violate exchangeability, but do not affect the interpretability of a regression per se. Rather, exchangeability represents a criterion by which a researcher can evaluate his modeling choices. If a researcher believes that the errors in his model are not exchangeable, then good empirical practice requires that he consider whether the violations invalidate the substantive claims for which the model will be used. This inevitably requires judgment, but judgments are part of any substantive empirical exercise. Draper et al. (1993) place judgments of exchangeability at the heart of empirical analysis and discuss how data may be used to assess these judgments. Brock and Durlauf (2001) place exchangeability judgments at the center of a general critique of empirical research on growth. This emphasis on judgment helps explain why exchangeability notions are more common in Bayesian contexts than in frequentist contexts; exchangeability captures the notion of what is meant by a researcher’s subjective beliefs that a sequence is a random sample from a population (see Lindley and Novick 1981 for elaboration and links to De Finetti’s original thinking).

Exchangeability has recently been shown to have important uses in econometric theory. Donald Andrews (2005) developed a theory for asymptotic inference in cross-sections that addresses the long-standing problem of cross-sectional residual correlations. Unlike the time-series case, a cross-sectional index does not provide a natural ordering across random terms, so there is no reason to think that dependence across residuals diminishes as the difference between their respective indices grows. Andrews shows that if this dependence is generated by a set of common shocks so that, conditional on the shocks, the errors are independent, one can develop a range of asymptotic results. This independence is motivated in turn by exchangeability arguments. This mode of analysis suggests that exchangeability may play an increasingly prominent role in econometric theory.

Existentialism

“Existentialism” refers to a loosely knit movement holding, in the words of Jean-Paul Sartre, that “existence comes before essence.” This proposition should be understood in opposition to both rationalism and empiricism. Both philosophies, existentialism argues, overlook the unique character of being human, of being an “existent” thrown into a world without pregiven meaning or significance. Moreover, the human condition is such that it does not fit into even the most exhaustive system of objective concepts. Instead, it calls for a new language of analysis that finds its expression in the works of not only Sartre but also Simone de Beauvoir, Albert Camus, Maurice Merleau-Ponty, Jean Wahl, Karl Jaspers, Martin Buber, Gabriel Marcel, Miguel de Unamuno, José Ortega y Gasset, Nicholai Berdyaev, and Lev Shestov.
These thinkers—some of whom rejected the label “existentialist”—found inspiration in the philosophies of a long list of forerunners. The most important ones are Søren Kierkegaard’s anti-Hegelian philosophy and Martin Heidegger’s phenomenological ontology. Common to both philosophies is the idea that being human is an “issue” for itself, that is, that the specter of death (finitude) makes it all-important how we interpret the primal nature of our own being—what Heidegger refers to as Dasein. The condition of Dasein is an ecstatic and angst-inducing one. To begin with, it discloses the historicity of our beliefs and habits, which in turn points to the openness of Being itself. But it also reveals the absence of a shared anchor—an infinite void or fundamental nothingness—challenging philosophy’s pretense to know the nature of our moral obligations and political responsibilities. Kierkegaard enacts the fear that follows from this challenge through an analysis of cases such as Abraham’s sacrifice of his son, a case in which God’s commandment is comprehensible, not as a universal law pertaining to all, but as an injunction addressed to Abraham in his singularity.

The tension between the ecstatic and the fearful is important to the way in which existentialism approaches its main themes: intentionality, intersubjectivity, meaning, and human freedom. One line of research—associated with theologians such as Karl Barth and Paul Tillich—interprets these themes from a theistic perspective according to which the affirmation of God, although itself an act of madness, is the proper answer to the meaninglessness of contemporary existence. Another line—perhaps better known—entails a turn to atheistic humanism. Sartre dramatizes this turn in his 1944 play Huis Clos (No Exit). At issue in this play is the way in which individuals take responsibility for their own lives. The play revolves around three strangers who confront the singularity of their deaths in a room that has no significance, no signs of some higher Being. The result is not only a sense of absurdity—one that reveals the inauthenticity of everyday life (whether lived in a bourgeois manner or not)—but also a need for turning this absurdity into a cause for engaging one’s own life head on. We must transcend the contingency of our surroundings in order to become authentic beings. As Inez, one of the three main characters in the play, says, “You are—your life, and nothing else.”

Although significant, it is important not to overstate the differences between the atheistic and theistic brands of existentialism. Both brands criticize the church’s appropriation of God; and both brands emphasize living an authentic existence through an encounter with a transcendent of some sort. The political implications that impinge on existentialism’s analysis of the human condition, then, are first and foremost related to the concepts of freedom and free will. Humans are free in the sense that (1) neither God nor any value or command binds their choices, (2) their concept of selfhood hinges on the intentional activity directed toward things in the world, and (3) reality proper is what follows from this kind of activity. While this may give the impression that existentialism is committed to an individualistic ideology, it is important not to mistake the affirmation of freedom (and free will) for a lack of interest in criticizing the liberal state. Because humans are free, and because they constitute reality through their own undertakings, they must also take active responsibility for society as a whole. The existentialist movement translates this responsibility into an often Marxist-inspired critique of male domination, technology, and capitalism.

EXIT, VOICE, AND LOYALTY
To extend the analysis of his fellow economists beyond their traditional focus on simple market exchanges, Albert O. Hirschman wrote Exit, Voice, and Loyalty (1970), a seminal work that examines how several different kinds of human behavior might be invoked when consumers confront a decline in firms, organizations, and states.

EVL MODEL
In Hirschman’s exit, voice, and loyalty (EVL) model, consumers dissatisfied with a product in the marketplace, for example, might complain to the producer about declining quality (voice) or patiently wait for the product to improve (loyalty) instead of purchasing a rival good or service (exit). In politics, voters dissatisfied with their party’s policies may vote for another (exit), work in party
caucuses to change those policies (voice), or hope that the party platform will be revised (loyalty). And in an abusive interpersonal situation, one can leave (exit), complain (voice), or avoid confrontation in the hope that the storm will pass (loyalty). Indeed, Hirschman’s analysis of the interrelations among various behaviors an individual might engage in when confronting declining quality in one’s personal, political, economic, and social relationships was significant to all of the social sciences precisely because of its comprehensiveness.

If very different types of behaviors can effectively substitute for each other, one cannot study each independently without missing something vital. Voice behaviors like consumer complaints or writing letters to the city council, for example, cannot be understood without accounting for opportunities to exit through purchasing a substitute product or moving to another city. Hirschman further demonstrated that opportunities to exercise one type of behavior often influence—in sometimes very surprising ways—the effectiveness of other behaviors. The threat of exit, for example, may encourage declining firms, organizations, and states to be more or less attentive to voice depending on who is exiting, when the exiting occurs, and how it bears on the interests of those making decisions about their goods, services, or policies.

WEAKNESSES
Despite its sweeping and immediately recognized import, Hirschman’s analysis is nonetheless incomplete. First, the EVL model does not give equal attention to the three types of behaviors; loyalty only makes an appearance two-thirds of the way through the analysis. In addition, loyalty is discussed almost exclusively as a brake on the exercise of exit and voice rather than as an independent mode of response to dissatisfaction. Second, exit, voice, and loyalty fail to encompass all of the possible behaviors that one might observe when consumers, voters, or family members confront a decline in the quality of their relationships. They may well do nothing. Indeed, Hirschman discussed how consumers might neither exit nor engage in voice behaviors when institutions do not provide producers with incentives to respond to consumer demand. However, he essentially treated such situations as pathologies rather than incorporating them into the model in a systematic manner, recognizing thereby that not responding to decline is potentially as interesting as exit, voice, or loyalty. Third, Hirschman did not develop a general model that communicated how consumers, voters, employees, or family members select among exit, voice, or loyalty behaviors.

CONTEMPORARY SCHOLARSHIP
In the early 1980s scholars addressed these weaknesses in extensions of Hirschman’s EVL model. First, in their 1983 analysis, Caryl Rusbult and I. M. Zembrodt recast Hirschman’s threefold typology as a two-dimensional space. The first distinguishes active and passive responses to dissatisfaction while the second distinguishes constructive and destructive responses. Thus, voice includes all active responses to dissatisfaction that are constructive with respect to the relationship giving rise to that dissatisfaction. In contrast, exit behaviors, while also active, are destructive to the relationship. Loyalty behaviors are passive, constructive responses to dissatisfaction. A fourth type of response not addressed by Hirschman except as pathological behavior is neglect; that is, passively responding to dissatisfaction by allowing the relationship to further deteriorate. In another significant extension of Hirschman’s analysis, in 1981 Daniel Farrell and Rusbult developed a parsimonious, three-variable model explaining how individuals select among the responses to dissatisfaction. When one has many alternatives to a current job, a product or service, or a romantic partner, one is more likely to respond to dissatisfaction in an active manner through voice or exit rather than through the passive behaviors associated with loyalty or neglect. But when one is highly invested in and/or has had a high level of prior satisfaction with the relationship, one will more likely respond to dissatisfaction with constructive voice or loyalty behaviors and suppress negative behaviors characteristic of exit and neglect responses.

A number of social scientists continue to employ Hirschman’s original threefold typology. By the mid-1980s, however, many others were employing its descendant, the exit, voice, loyalty, and neglect (EVLN) model. This extension of the original highlighted two dimensions defining four distinct responses to dissatisfaction, including the previously neglected category of neglect. Selection among the four responses was further hypothesized to be function of alternatives, prior satisfaction, and investments. The EVLN model was strongly supported in empirical work on private and public sector employment behaviors, romantic relationships, and political behavior in metropolitan settings. All of these studies examine a wide range of responses to dissatisfaction within a common theoretical framework linking what had been previously understood as disparate and distinct behaviors.

There have been fewer applications of either the original version of Hirschman’s model or its EVLN extension in studies of traditional market economics, which was the main focus of Exit, Voice, and Loyalty. To some extent, this reflects some long recognized normative biases in the disciplines. In the same way that some political scientists might regard exiting a political jurisdiction as illegitimate to the point of constituting treason, some economists view voice, loyalty, or neglect as a failure on the part of consumers to exercise due diligence or as evidence of imprudence. But perhaps a more telling explanation, and
one applicable to all social sciences, is that simultaneously accounting for exit, voice, loyalty, and neglect behaviors is very hard to do.

EXIT POLL
Exit polls are surveys based upon voter interviews immediately after they have finished voting. The exit polls play a significant part in media projecting election winners and their margin of victory. The polls are used mainly in major elections, usually concerning national or state candidates. Exit polls are part of the pervasive status of surveys and polls in American and other societies. Exit polls have been used in elections throughout the world, such as in 2005 in the Belarus and Ukraine and 2006 in Mexico. Media organizations purposely utilize exit polls to understand voters’ choices and explain issue, partisan, and demographic differences in electoral outcomes. This information serves as a means of validating elections.

Exit polls are highly accurate because they remove main elements of potential survey research error problems by accounting for who actually votes and avoiding undecided voters. Problems for exit polls include a sample estimate of voter turnout, which may be incorrect for one or more candidates. Further, these polls do not consider absentee voting and other forms of early voting that do not require individuals to be at a polling place.

HOW CONDUCTED
An exit poll is conducted by selecting sample precincts in a state or other electoral area based upon historical voting data to judge outcomes of voting data. In each of the selected precincts, an interviewer requests a voluntary interview from a systematically selected voter; for example, every third or every tenth voter. Each voter completes a thirty-to forty-item questionnaire, which is placed in a box.

In each election cycle new questions are developed. The information is collected, tabulated, and transmitted to a central facility that tabulates a state or other electoral area total. In the 2004 U.S. presidential election nearly 150,000 people in nearly 1,500 precincts were interviewed in every state except Oregon. In 2004 the National Election Pool (NEP) also conducted a national sample of polling places to supplement exit poll data.

Prior to the 1990 U.S. midterm elections, each major network—ABC, CBS, NBC, CNN, and the Associated Press—conducted separate exit polls. For financial reasons, they created a consortium (also joined by Fox News) to conduct a single national exit poll, called News Election Service, and later called Voter News Service. After problems encountered with the 2000 presidential election, the 2004 presidential election exit poll was conducted through NEP by Edison Media Research/Mitofsky International. Exit polling results are delivered in three different times during election day, including mid-afternoon on that day. Multiple national exit polls can have different results based upon different sampling frames and different polling places. In other nations, major media organizations sponsor similar survey organizations to conduct exit polls. Media networks use exit poll data and actual vote returns from some exit poll sample precincts to project electoral victors. To project the outcome, exit poll findings must exceed the margin of sampling error in the sample design, generally plus or minus 4 percent at a 95 percent confidence level for state polls, and plus or minus 3 percent at the same confidence level for the national exit poll. Data within the sample design parameters is "too close to call."

PROBLEMS WITH U.S. PRESIDENTIAL ELECTIONS
High profile exit polls in U.S. presidential elections have encountered difficulties in analysis and reporting of information, especially in the 1980, 2000, and 2004 elections.
In 1980 television networks correctly predicted Ronald Reagan's victory over President Jimmy Carter prior to many election polls remaining open in the midwestern, mountain, and western states. Individuals argued that this projection diminished those individual's willingness to vote. In 1985 Congressional hearings—U.S. House Task Force on Elections—were held and resulted in network executives voluntarily promising to not release exit poll or election projections for a state prior to its poll closing time.

In 2000 the winner of Florida's twenty-five electoral votes would obtain the majority of national electoral votes and be the victor. On several occasions networks changed their exit poll projection for this state. First, they projected Democratic vice president Al Gore, then retracted their projection as actual vote return data arrived. At approximately 2:00 a.m. Eastern Standard Time (EST) they projected Florida for Republican George Bush, and about an hour later retracted it. Bush won Florida by 527 votes after a U.S. Supreme Court decision. The Florida vote was “too close to call” through exit polls, and individuals incorrectly reported their vote based upon the “butterfly ballot” or other difficulties, such as hanging chads.

In the 2004 Presidential election, there was confusion and controversy concerning reliance upon exit polls. As late as 9:15 p.m. EST, NEP indicated that Senator John Kerry was leading President Bush, 51 percent to 48 percent. The final outcome was President Bush 51 percent and Kerry 48 percent. It has not been clearly determined why the exit polls overstated the Kerry vote in several states.

**EXOGENOUS AND ENDOGENOUS VARIABLES**
**SEE** Variables, Predetermined.

**EXOTICISM**
The term exoticism describes a cultural phenomenon that projects Western fantasies about profound cultural differences. It adopts a cultural perspective that is firmly entrenched in the conventions and belief systems of Western civilization and therefore constructs the East as the archetypical location of otherness.

Exoticism demonstrates itself in colorful spectacles of otherness purporting to be an unmediated expression of natural drives and instincts. Although exoticism is associated with notions of animality, it carefully distances itself from the violence and exploitation that characterize the related concept of barbarism.

Notions of the exotic are associated with the lush vegetation of the tropics, geographically positioned between the Tropics of Capricorn and Cancer. They conjure up ideas of a bountiful nature, fertility, and uninhibited sexuality. An abundance of colors, sounds, smells, and tactile experiences promise to gratify the senses within an economy that gives free rein to consumption, unrestrained by political responsibility and ethical commitment to the real actors of exotic fantasies: that is, it disregards the role of disadvantaged people, coming mainly from third-world nations, who make a meager living from appearing in the dramatized fantasies staged in tropical holiday resorts and nightclubs.

The exotic first emerged as a concept in Western history when European nations began to explore and appropriate far-flung parts of the world. It experienced its first boom during the age of Enlightenment, when the establishment of trade routes began to supply Europe with such vast quantities of exotic goods that the purchase of luxury goods, including china, silk, perfumes, and precious stones, became affordable by the increasingly wealthy middle classes. This period also engendered a taste for the rich costumes of the Orient, the main geographic location of Enlightenment fantasies about the exotic. The fashionable Lady Mary Wortley Montagu, for example, had her portrait painted in a Turkish costume; the dissemination of stereotypes about the supposedly effeminate Orientals allowed her to appropriate the male garment of the turban without this being viewed as an act of cross-dressing.

The attempt by the age of Enlightenment to study and describe the vast number of different peoples of this earth was thus soon reduced to a mere interest in costume and other extrinsic markers of otherness, which were eagerly displayed in the European homelands. The demand of the nineteenth century for information about non-European peoples gave rise to numerous cheap reproductions of ethnographic drawings. Such easily affordable, popular publications, in their turn, further reduced cultural otherness to a matter of costume, which, among other things, suggested that supposedly primitive natives of, for example, Australia could be forced to abjure their traditional identity merely by donning the clothes of a European gentleman. The fact that nineteenth-century...
educational fantasies.

economic fantasies.

photographs of indigenous people wearing the clothes of their colonial masters now strike us as more exotic than early photographs of nonwesternized, indigenous communities reminds us that exotic fantasies entail a contrast of, and hierarchy between, two different cultures, controlled by the Western point of view.

For the twenty-first century, the experience of the exotic frequently thrives on an imitation of a ritual presumed to be authentic, involving an act of mimicry whose comic potential is easily glazed over. Performances of corroborees and other cultural practices can therefore be staged for tourists while the traditional rituals are on the brink of extinction.

The exotic also notably unleashes the sexual desires of repressed Westerners. Prostitution and the exploitation of countless women, children, and some men are side effects of exoticism’s tendency toward aesthetic abstraction and voyeuristic commodification of its participating actors.

Spaces set aside for expatriate consumption in international four- and five-star hotel chains (such as the Safari Bar in the Hyatt in Muscat, Oman) promise a sanitized encounter with a non-European subject that guarantees the absence of emotional involvement. Westerners, along with a westernized global elite, interact with one another against the background of scenery that refrains from challenging their privileges and supposed superiority.

Exoticism, as a cultural phenomenon, has mainly been examined via related critical concepts. Of special importance is Edward Said’s description of Orientalism as a discursive construction of European fantasies. Said’s study of Europe’s most enduring exotic fantasies about the Middle East set the beginning for other postcolonial interrogations of romanticized projections of the cultural other by which the West continues to assert its superiority. Homi Bhabha and subsequent scholars of hybridity and the encounters between subaltern and dominant cultures, therefore, make every effort to draw attention to exoticism’s parodic dimension in order to empower and render eloquent its latent subversion of oppressive and exploitative fantasies.

EXPECTATIONS

Economics is concerned in large part with expectations. Consumers planning to smooth their spending over a lifetime form expectations about future income, prices, interest, and other factors in their decision-making processes. Producers spreading investment expenditures over future time periods form expectations of future costs and returns. Government policy makers aiming to stabilize the economy use monetary and fiscal policies to achieve their expected targets. In the global economy, gains from free trade occur because traders expect a country to produce at the lowest opportunity cost. Economists try to measure expectation, to analyze their effects on the economy, and to study how they are formed.

In a competitive economy, expectations are realized at the equilibrium state. A Keynesian view of expectation equilibrium is that planned savings should equal planned investments. One reason that expectations may not be correct in a competitive economy is that prices and output vary, creating problems for producers who incur costs now and are uncertain about future prices. One can analyze uncertain outcomes in order to assign a probability or likelihood to their occurrences. If uncertainty is too risky, one may choose to be risk averse, as in the case of oligopolistic firms that are unable to guess their rival’s conduct. To understand and coordinate expectation, one can collect anticipation data on business plans, ask people about their expectation and attitude, or survey experts to learn about their consensus.

One forms expectations with the aid of logic, psychology, and probability. Cognitive psychologists, for instance, found that agents make future decisions based on the similarity of present evidence, playing down probabilities and even the quality of the evidence. An expected outcome may follow from conscious behavior or habits, which may be self-fulfilling, nonmaterial, and altruistic.
Agents may be content with little achievements, not necessarily looking for maximum outcomes. An individual may be certain of his or her expectations. Certainty means one assigns a high probability or likelihood to the occurrence of the event. Besides high and low probability events, one finds some uncertain events to which one cannot possibly attach a probability. One distinguishes between measurable and unmeasurable uncertainty, assigning the term risk when uncertainty can be measured.

A workhorse in expectation analysis is the expected utility hypothesis (EUH). The EUH is a function that captures all of an individual’s expectations about an outcome, assigns a numeric value for one’s choices among alternatives, and allows one to maximize the expected outcome. But its results can be paradoxical. The St. Petersburg paradox, a “let’s make a deal” situation, offers the player a fixed amount of money (say $20), or an uncertain outcome that pays one dollar if heads turn up when a fair coin is tossed N times. The outcome is 2^N, each with a probability of one half, so that the expected value of the game is infinite, the limit of \( \sum_{n=1}^{\infty} (1/2^n)(2^n) \). The paradox is that no one is willing to pay a large sum to play the game. The probabilist Daniel Bernoulli (1700–1782) thought that the problem was that as a person wins more and more money in the game, one experiences diminishing returns for money. To capture diminishing utility, Bernoulli used a log utility function on the outcome, showing that the payoff becomes a small sum: \( \sum_{n=1}^{\infty} (1/2^n)(\log 2^n) = \log 4 \). The solution was not definitive in the sense that one can choose a utility sequence that would still yield an infinite payoff. What is needed is a bounded utility function.

From a microeconomic perspective, the economist Milton Friedman presented a lucid explanation of the utility concept that has telescoped further development. With a stream of income, \( I_s \), and associated probabilities, \( P_i \), the expected value is the sum of their products. Utility enters when one forms a function of income, \( F(I) \), whose products with their respective probabilities give a special function, \( G = \sum_{i=1}^{\infty} P_i F(I_i) \). In the special instance where income is expected with certainty, \( P_i = 1 \), both the \( G \) and \( F \) functions have the same value or utility. A plot of \( F(I) \), against, income, \( I \), highlights a concave or convex utility function, indicating risk aversion, and risk lover (plunger), respectively. A risk averse person prefers the expected value over the EUH outcome. A risk lover prefers the EUH to the expected value. If one eliminates scale and origin from the utility function by the restrictions \( I = 0, F(I) = 0, \) and \( I = 1, F(I) = 1 \), then one can determine utility values for any amount of income. Without such restrictions, however, the utility function can take on a recurrent concave shape, explaining why someone will not pay a large sum to play the St. Petersburg game.

From the macroeconomic perspective, one starts with the English economist John Maynard Keynes’ equation where national income, \( \phi(N) \), equal to investment demand, \( D_i \), plus consumption \( \chi(N) \), could be solved for full employment, \( N \). Given the state of employment, consumers, investors, and employers expect to consume, invest, and earn a prospective amount, respectively, which fluctuates with the state of long-term expectation. Keynes’ concept of long-term expectation can be clothed in modern notations. Long-term expectation takes the form of a random variable, \( y \), within a time frame of three months to a year, \( t \), in a mass psychology “atmosphere”, \( \omega_{it} \) given state of the news, \( \Omega_{it} \). Investors, \( i \), calculate the average expectation, \( E \), such as in a beauty contest where competitors must pick out the prettiest face among photographs that are published in a newspaper. In this competition, the average is an intersubjective representation, which may be expressed as \( y_{it} = \lambda_i E[y_i|\Omega_{it}] + \omega_{it} \) and the competitor whose choice comes nearest to this average will win the competition.

Keynes’ work created several research programs in expectations. John Hicks used a day-to-day model for up to a week to develop his elasticity of expectation hypothesis. Following Hicks in dating commodities, the Arrow-Debreu model of competitive equilibrium found current and expected prices that jointly clear supply and demand equations in present and future markets, and Jean-Michael Grandmonth formulated an intertemporal model, that extended the Arrow-Debreu model for sequences of time periods. On the other hand, G. L. S. Shackle steered expectation analysis away from a probability base. One makes several nonprobabilistic statements about the next period output, \( x \), such as that it is impossible, possible, surprising if it would reach a specified high or low level, or very surprised it occurs. One can attach a corresponding number, \( y \), to represent the degree of potential surprise those outcomes mean. One can further place a corresponding number on the surprise value when it reaches a maximum potential surprise, \( \bar{y} \). The result is a function \( y = f(x) \) that is bowl shaped, and centered at a neutral output level where \( x = 0 \). Further, one can assign numbers to the degree of surprise numbers to measure the degree of stimuli, \( A(x, y(x)) \), from the surprise function associated with the potential outcome.

Since the 1950s, economists have been using an adaptive expectation model to show how expectation is formed over time. The adaptive version follows the dictum that an individual learns from his or her mistakes. A rifleman calibrates his weapon by observing how far off his previous shot deviated from the target.
In macroeconomic forecasts, the adaptive model was employed to study the effect of expected prices and unemployment on present wages and inflation rates. In the Phillips Curve, the coefficient of the expected price variable was zero. A coefficient of the expected price variable equal to one would mean that expectations are fully adjusted into inflation and wage rates. For instance, if the expected rate of inflation, π̂, is set by some proportion, γ, between the actual inflation, π, and the expected inflation, then one can use the equation: π̂ = π̂t−1 = γ(πt−1 − π̂t−1).

0 < γ < 1 to represent the formation of expectations. Full adjustment means γ = 1, but empirically it was mostly less than unity, implying that the Phillips Curve was downward sloping.

The adaptive expectation model was integrated into the MPS model of the Federal Reserve Board, one of the first large-scale econometric models that were built in the 1960s. Expectation was captured in the form of lag structure both to parameters and error terms. The model, however, failed to capture drifts in the parameters of structural equations. The Rational Expectation Hypothesis (REH) has explained some of those problems and added other novelties to the formation and measurement of expectations.

The concept of REH is based on equilibrium analysis as opposed to Keynesian disequilibrium analysis. Under ideal conditions of competition, one expects economic agents to have perfect information or knowledge of the relevant market variables. Absent complete information, one settles for all the information that is available before making a forecast.

Robert Lucas is credited with making the REH practical. One incorporates information into REH models by replacing the expected variable with an equation or variable that measures the expectation. For instance, Thomas J. Sargent and Neil Wallace wrote equations for Aggregate Supply, IS, LM, and monetary policy. Some of the equations require that the expected price level prevailing at time t be set at time t − 1. In other words, one replaces the expression of the form E[p^t | Ω^t] with values resulting from applying the mathematical expectation operator, E, on them, conditioned by the information one has at the time t − 1.

Faith in the RE hypothesis is still being determined. Edmund Phelps advocated dropping the equilibrium framework, for a more non-Walrasian framework in which economic agents are not price takers, which yields results more in line with Paul A. Samuelson’s views that oppose the REH. Large-scale econometric models for the REH are still not within reach. To improve predictions, Finn Kydland and Edward Prescott have used time-consistent computational experiments in econometric models, subsequent to the REH revolution. These models allow policy makers such as the Federal Reserve Board, to have no concern about wrong models or wrong goals, or even histories and reputation, because they need only choose sequentially.

**Expectations, Adaptive**

**Expectations, Implicit**

The concept of implicit expectations, which was pioneered in 1954–1955 by Edwin S. Mills, circumvents a problem encountered by economists who study the behavior of business enterprises: Although production and pricing decisions are made on the basis of expectations about future economic conditions, economic researchers must cope with a shortage of observations on actual sales anticipations. One research strategy is to work with explicit assumptions about the way expectations are formed. Thus, in 1953 Robert Ferber concluded on the basis of his examination of empirical evidence in the Railroad Shipper's Forecasts that expected sales are equal to actual sales of the same period of the preceding year adjusted for recent trend. In contrast, Mills did not attempt to model the process by which expectations are generated. His implicit expectations approach substitutes the actual realized sales—the sales turn out to be—for the unobserved expected sales under the assumption that the forecast error is random. That is to say, 

\[ E_t - X_t = \varepsilon_t \]

where \( E_t \) is expected sales, \( X_t \) is actual sales actually turn out to be, and \( \varepsilon_t \) is a random error with zero expected value (it averages out to zero). Mills used his implicit expectations concept in a number of theoretical and empirical articles, including a 1957 study in which he was able to estimate the magnitude of undesired inventories generated by sales forecast errors made by American corporations.

Mills's implicit expectations approach is closely related to John F. Muth's (1961) concept of rational expectations that Robert Lucas invoked in 1972 in spearheading a revolution in the field of macroeconomics. Muth, like Mills, assumed that forecast errors are random. This is an example of independent discovery, as often is encountered in scientific research (Merton 1973), but a rather subtle difference may distinguish the two concepts. Expectations are implicit if the random forecast error \( \varepsilon_t \) is distributed independently of \( E_t \) but rational if they are distributed independently of \( X_t \). If a firm's sales anticipations are based on a random survey of customers about their expected demand, the error in forecasting total sales that results from sampling error will be distributed independently of what sales actually turn out to be; this means that the sample survey has generated an implicit forecast of sales. If instead a forecast is generated with data from prior years with a multiple regression of actual sales on

**Lall Ramrattan**

**Michael Szenberg**
observable variables, such as the unemployment rate, price, and sales in prior periods, the forecast will be rational because the errors of a correctly formulated regression forecast, as a mathematical necessity, are distributed independently of the prediction. Implicit forecasts can be converted into rational forecasts with the equation obtained from historical data by regressing the realization on the forecast.

In a paper published in 1985 Muth reported that his empirical investigations indicated that expectations are not rational: The forecast errors were correlated with the forecasts, and the variance of the forecasts was often larger than the variance of the variable that was being predicted. However, Muth found that the errors also were correlated with the actual realizations; that meant that they were not implicit expectations. He advanced as a synthesis an “errors in the variables” model that allowed the forecast error to be correlated with both the variable being forecast and the actual outcome but cautioned that this model was not fully in accord with the facts. Although Muth became skeptical about his own theory, it provides the foundation for macroeconomic studies of inflation and business cycle fluctuations.

EXPECTATIONS, RATIONAL

A basic postulate of economics is that people “do the best with what they have” (Maddock and Carter 1982). Applied to the formation of expectations (or economic beliefs), the theory of rational expectations, first proposed by John Muth in 1961, assumes that agents acquire and process information rationally. Since the 1970s, this theory has been used to model phenomena as diverse as aggregate supply, exchange rates, consumption, and economic cycles. A number of important empirical predictions—about exchange rates (Frankel and Rose 1995) and the term structure of interest rates (Mankiw and Miron 1986), for example—employ rational expectations as a key assumption.

RATIONAL EXPECTATIONS: DEFINITIONS AND DEFENSES

Definitionally, a rational expectation is the best guess about an unknown variable, using all available information. Where the unknown variable is random (such as the exchange rate in $k$ periods time represented in equations by $y_{t+k}$) the rational expectation is the mean of the variable (i.e., the mathematical expectation $E(y_{t+k})$ equal to the integral of all possible values of $y_{t+k}$, weighted by their probabilities). The rational expectation is calculated using information up to the current period $t$, and so it is sometimes written as $E(y_{t+k}) (k > 0)$. Obtaining the mathematical expectation within a model context requires knowing the full structure of the model. If information is costly to collect, then rational expectations cannot strictly be rational, as was recognized soon after rational expectations was proposed. In other words, assuming a positive marginal cost to information and a decreasing marginal benefit, the information collected will fall short of the information required to understand the full system.

The economics literature either ignores this problem for simplicity, or it acknowledges that expectations are formed on the basis of sample information. In the latter case, the rational expectation can be defined as an estimator of an unknown variable with desirable statistical properties, such as minimum forecast error (in the case of a random variable) or unbiasedness and efficiency (in the case of an unknown parameter). Alternatively, mirroring the use of estimators in classical inference, changes in beliefs about unknown parameters can be modeled by statistical hypothesis testing (Menzies and Zizzo 2005).

It is assumed that people do not make systematic errors when predicting the future, so the rational expectation of a random variable is the mean represented by $E(y_{t+k})$. In other words, departures from perfect foresight (that is, from $E_{t}(y_{t+k}) = y_{t+k}$) are a random process with
a zero mean. Mathematically, rational expectations are modeled by making the outcome $y_{t+k}$ equal to the rational expectation, plus a random error $u_{t+k}$ representing ignorance, mistakes, and other influence only revealed in $k$ periods time: $y_{t+k} = E[y_{t+k}] + u_{t+k}$.

As an example of rational expectations at work, if all agents hold rational expectations, if transactions costs are small, and if agents are unconcerned about risk, then the so-called efficient market hypothesis holds. If a security’s price does not reflect all the information available about it, then someone can buy (or sell) the security to make a profit, thus driving the price toward the rational expectation. If all profit opportunities are eliminated, prices in financial markets fully reflect fundamentals (e.g., future interest rates, profits, or dividends).

Rational expectations have a number of advantages as a modeling tool. First, they are conceptually simple. Second, they prevent economic theorists from introducing ad hoc influences via arbitrary expectations mechanisms. Third, they create simple model solutions. Fourth, there is a close correspondence between the properties of random errors arising from the rational expectations ($u$ above) and the random errors assumed in empirical work.

There are many ways of defending the notion that agents have rational expectations, based on rationality (rational agents should use all the available information in the most efficient way), macro-aggregation (rational expectations allow for mistakes, as long as they are not systematic mistakes), and evolutionary dynamics arguments (agents without rational expectations would be driven out of the market by more rational agents, who would be able to bankrupt them on the basis of their superior use of information). Even if these arguments are not accepted, however, mainstream economists could also claim that the parsimony and tractability of rational expectations justifies their use. While this is unlikely on its own to be sufficient to accept rational expectations as scientifically valid, it may be more palatable if one can claim that a lack of realism is an acceptable price when parsimony and tractability are matched by significant predictive power. The argument has also been made that it would not be safe to make policy on the basis of the assumption that policymakers have superior knowledge about how the economy works, and that macroeconomic models should therefore employ rational expectations (Sorensen and Whitta-Jacobsen 2005).

ARGUMENTS AGAINST RATIONAL EXPECTATIONS

There are a number of contrary views on rational expectations, however. First, rational expectations are rational only if collecting and processing information is costless in money and time, let alone cognitive effort. If agents are only boundedly rational, information collection and processing costs will be larger and will induce shortcuts in the use of information. Second, the theory of rational expectations assumes that agents not only hold a model of the economy, but that this model of the economy is correct. This is in stark contrast with the fact that disagreement exists within the economics profession on how the economy works. Further multiple models are normally used in practical policymaking. Interesting variations of rational expectations build on the assumption that agents do not know exactly how the economy works, so that they need to make hypotheses on models (or parameters of models) of how the economy works (Goldberg and Frydman 1996; Menzies and Zizzo 2005).

Third, there has been no general proof of the evolutionary dynamics argument. Indeed, there are models showing how less-than-rational agents may survive when mixed up with rational agents (e.g., noise trader models in finance; Shleifer 2000). Fourth, the usefulness argument is virtually unfalsifiable. This is because tests of rational expectations are also joint tests of the models they are embedded in, and because of the difficulty in identifying rational expectations relative to alternatives in regression analysis. Therefore, failures of rational expectations can be, and often are, blamed on other hypotheses (see, for example, Gerlach and Smets 1997 in relation to the term structure of interest rates), though the problem may ultimately lie in the model of expectation formation.

Fifth, in experimental settings, rational expectations predictions are not rejected as null hypotheses in some contexts, but the most common outcome is that individuals do not hold rational expectations. In addition, experimental research often finds either underutilization or overutilization of prior beliefs (Camerer 1995). These systematic empirical failures cannot be reconciled with the macro-aggregation argument.

Finally, if conservativeness in policymaking is considered desirable in the face of an uncertain economy, then it should be modeled explicitly (e.g., in the objective function), rather than by postulating an incorrect model of expectation formation. Doing otherwise may be counterproductive, and it may make it more difficult to provide an accurate account of the economy. Notwithstanding these points, however, the notion of rational expectations remains the mainstream conceptualization of expectations formation in economic modeling.

EXPECTATIONS, STATIC

In economics, the concept of static expectations describes an assumption that economists make about the way people form their predictions regarding the future values of economic variables. Specifically, the static expectations assumption states that people expect the value of an economic variable next period to be equal to the current value of this variable.

The concept of static expectations has been widely used in the early economics literature, such as in the cobweb model of price determinations. In the cobweb model, the static expectations assumption states that sellers expect the price of a good next period to be the same as it is today and adjust their production accordingly. The early literature did not focus much on unexpected shocks.

The concept of static expectations and its more advanced variation, the concept of adaptive expectations, play an important role in the monetary economics, the branch of economics that addresses the design and the impact of monetary policy. This concept was formalized in 1968 simultaneously by Milton Friedman (1912–2006) in his article “The Role of Monetary Policy” and by Edmund Phelps (b. 1933) in his article “Money-Wage Dynamics and Labor Market Equilibrium.” Because only unexpected inflation, or inflation rate in excess of the expected inflation rate, can increase the aggregate output of the economy, it is important for policymakers to know what inflation rate economic agents expect in the future. For economists this means that they have to make an assumption about how economic agents form their predictions of future inflation.

The most simple-minded assumption about expectations one can make is that of static, or naïve, expectations: Agents are assumed to expect the inflation rate next year to be the same as it was this year. Adaptive expectations assumption merely extrapolates the concept of static expectations—it suggests that economic agents expect the inflation rate to be equal to the weighted average of the inflation rate in the past few periods. Economists used the assumptions of static and adaptive expectations until the concept of rational expectations was developed.

The main criticism of the concept of static expectations is that it assumes that people ignore the information about possible shifts in policy variables. In case of monetary policy, if policymakers announce credibly that they will adopt an anti-inflationary stance, it would not be rational for economic agents to believe that the inflation rate will remain the same. Thus, rational expectations assumption incorporates all possible information available at the time the expectations are formulated, not just the past values of the variable being forecasted, as is the case with static or with adaptive expectations.

In modern economic theory most models that incorporate uncertainty about the future assume rational expectations, not static expectations. Nevertheless, some economic variables and many financial variables follow a specific stochastic process, called martingale, for which the best prediction of the future value is today’s value. For these variables static expectations turn out to be rational expectations.

EXPECTED UTILITY THEORY

Expected utility theory is a model that represents preference over risky objects, by weighted average of utility assigned to each possible outcome, where the weights are the probability of each outcome.

The primary motivation for introducing expected utility, instead of taking the expected value of outcomes, is to explain attitudes toward risk. Consider for example a lottery, which gives $100 and $0 with even chances, and a sure receipt of $50. Here typically one chooses the sure receipt, whereas the two alternatives yield the same expected return. Another example is the Saint Petersburg paradox. Consider a game of flipping a fair coin until one has a tail. When the number of flips obtained is \( k \), one receives \( 2^k \), which happens with probability \((1/2)^k\). The expected return of this game is \( \sum_{k=1}^{\infty} 2^k (1 / 2)^k = \sum_{k=1}^{\infty} 1 \), which is infinity. However, a typical decision maker is willing to pay only a finite amount for playing this game.

The theory resolves this problem by taking risk attitude into account. Here a risky object is a probability distribution over outcomes, denoted by \( p \). Then the expected utility representation takes the form \( U(p) = \sum u(x_k) p_k \), where \( p_k \) is the probability that outcome \( x_k \) is realized, and function \( u \) expresses the utility assigned to each outcome. Notice that \( u(x) \) may not be \( x \) as it is, and the curvature of \( u \) explains the decision maker’s risk attitude. When the graph of \( u \) is convex to the top, one has the formula \( 0.5u(100) + 0.5u(0) < u(50) \), which explains the first example (similarly for the second). When this is the case, the decision maker is said to be risk averse. Expected utility theory enables empirical analysis of choice under uncertainty such as financial decision, by quantifying the degree of curvature of \( u \).

The theory originates from Daniel Bernoulli (1700–1782), an eighteenth-century mathematician, and was given an axiomatic foundation by John von Neumann and Oskar Morgenstern in the 1940s. They started from a preference ranking of probability distributions over outcomes, and provided the condition for its expected utility representability. The condition consists of three axioms: weak order, continuity, and independence. The most prominent axiom is independence: when the decision maker prefers distribution \( p \) to distribution \( q \), then he or she prefers the distribution made by mixing \( p \) and any another distribution \( r \) with proportion \( \lambda \cdot 1 - \lambda \), that is \( \lambda p + (1 - \lambda)r \), to the distribution made by mixing \( q \) and \( r \) with the same proportion, that is \( \lambda q + (1 - \lambda)r \). Here \( \lambda p + (1 - \lambda)r \) refers to the distribution that assigns probability \( \lambda p_k + (1 - \lambda) r_k \) on each outcome \( x_k \) respectively. Informally speaking, when \( p \) is preferred to \( q \) then having “\( p \) with probability \( \lambda \) and \( r \) with probability \( 1 - \lambda \)” will be preferred to having “\( q \) with probability \( \lambda \) and \( r \) with probability \( 1 - \lambda \),” since the difference lies only in \( p \) and \( q \).

The theory is extended to subjective expected utility theory, where the probabilities are not given objectively, but the decision maker is to hold a subjective belief over relevant events.

Various criticisms to the expected utility theory motivate further developments, two of which are explained in this entry. The first criticism is that the independence axiom may be violated systematically, which is referred to as the Allais paradox. Consider for example a bet, which gives $120.00 with probability 0.9 and $0 with 0.1, and a sure receipt of $100.00. The typical choice here is to take the sure receipt. Now consider two bets, one gives $120.00 with probability 0.45 and $0 with 0.55, the other gives $100.00 with probability 0.5 and $0 with 0.5. Here the typical choice is to take the first bet. This violates independence since the second two bets are made by mixing the first two with the lottery that gives $0 for sure, with even proportion. One explanation of this is called certainty effect, that an outcome is overweighted when it is sure than when uncertain.

The second criticism is that risk attitudes may depend on status quo points, whereas the theory assumes that only the distributions over final outcomes matter. Suppose for example that the decision maker is given $1,000 initially and faces two alternatives, one gives $200 more and $0 (no change) with even chances, the other gives $100 more for sure. The typical choice here is to take the sure gain, which exhibits risk aversion. On the other hand, suppose one is given $1,200 initially and faces two alternatives, one yields a $200 loss and $0 with even chances, the other yields a $100 loss for sure. Now the typical choice is to take the risk, which exhibits risk loving, while the distributions over final outcomes are identical across the two comparisons.

These anomalies, together with other ones, motivate various models of nonexpected utility.

Takashi Hayashi
Experiments

At the most basic level, social science is the process of developing and testing scientific explanations for various aspects of behavior and experience. Of the possible types of explanations, causal explanations are generally preferred in science because they specify why some phenomenon occurs rather than simply indicating that or when it occurred. This focus on causation allows scientists to predict and, in some cases, control phenomena. Other types of explanations, although important, are far less adept in this regard. A preference for causal explanations has led researchers to develop special procedures for testing putative cause-and-effect relationships, collectively known as experimental methodology.

Rationale and Structure of Experimental Methodology

Experimental methodology affords an inference of causality through a collection of specific procedures. First, the researcher creates two or more groups of research participants that are equivalent at the outset of the study. Second, the researcher introduces different levels (e.g., doses, versions, intensities) of an independent variable to each group of participants. An independent variable is the entity, experience, or situation, for example, that the researcher proposes as the “cause” in a cause-and-effect relationship. It is referred to as “independent” because the experimenter has independent control over the specific group of participants that gets one level or another, and as a “variable” because it has more than one level (e.g., more than one dose, version, intensity, etc.). After introducing a different level of the independent variable to each group of participants, the researcher then measures or records at least one dependent variable—that is, the behavior, experience, or event that the researcher proposes as the “effect” in a cause-and-effect relationship. It is referred to as “dependent” because its outcome depends upon the effects of the independent variable and as a “variable” because it has more than one value.

The logic of this arrangement and the ability to infer a causal relationship from an experiment are straightforward. If the groups of research participants were equivalent at the beginning of the study and the level of the independent variable was the only thing that differed systematically among the groups, then any difference found on the dependent variable must be attributed to the causal influence of the independent variable on the dependent variable. Beyond the logic of experimental methodology, a number of issues may arise when constructing experiments that complicate matters considerably.

Creating Equivalent Groups

An important aspect of conducting an experiment is creating groups of participants that are equivalent prior to the introduction of the independent variable. There are two general strategies for accomplishing this equivalence—random assignment and blocking. Random assignment refers to the placement of each participant into one group or another on the basis of chance alone. This can be done by flipping a coin, consulting a random number table, or by using some other randomization technique to determine the specific group to which a participant is assigned. Random assignment has been called the “great equalizer” because any differences among participants prior to the introduction of the independent variable tend to be distributed equally across experimental groups.

The second strategy for creating equivalent groups is blocking, which refers to the practice of creating equivalent groups of participants by controlling for participants’ characteristics that could potentially have a systematic effect on the dependent variable. Such control can be accomplished in a number of ways, but the two most common strategies are matching and statistical elimination. With matching, the researcher assesses participant characteristics that may influence the dependent variable, purposely creates pairs of participants that share those characteristics, and then assigns one member of the pair to one group and the other member to another group. With statistical elimination, the researcher measures participant characteristics that may influence the dependent variable, and uses statistical techniques to mathematically remove the effects of those characteristics from the dependent variable. Of the two techniques, matching is better suited to research designs with only two groups, whereas statistical elimination can be used in research designs with two or more groups.

Operational Definitions

The independent and dependent variables are hypothetical constructs that carry with them conceptual definitions that researchers use to communicate information about the variables to other researchers. In order to conduct an experiment, however, the hypothetical construct must be made “real” by developing a strategy that will allow the independent variable
to be manipulated and the dependent variable to be measured or recorded within the experimental context. The process of making hypothetical constructs real is called operationalization. To operationalize a hypothetical construct, a researcher must select or create a concrete, real-world manifestation of the construct and define it with enough precision so that other researchers can identify it within the context of the experiment and, should they so choose, use the same operationalizations in other research projects.

A researcher can select from a number of options in order to operationalize the independent variable. Among these options are manipulations of participants’ physiological states (influencing the natural biological states of participants), environmental context (altering the situation or context in which participants are engaged), and blocking (dividing participants into groups or categories on the basis of certain characteristics such as age, gender, income, education level, etc.). Blocking is not a manipulation in the strict sense of the term, but naturally occurring differences among individuals can be used as a quasi-independent variable. Although many options for operationalizing independent variables are available, some may be more appropriate than others to the phenomenon at issue, and the final choice of operational definition is typically determined by the phenomenon in question, resources available to the researcher, and ethical considerations.

The researcher also has many options from which to choose when operationalizing the dependent variable. The research may measure the presence, frequency/intensity, or latency/duration of participants’ thoughts, beliefs, attitudes, behaviors, or behavioral intentions. Again, although many operational definitions are available, the final choice is typically determined by the phenomenon in question, resources available to the researcher, and ethical considerations.

Replication The operational definitions used in an experiment are important not only for communicating how variables are manipulated and measured in the context of a study, but also for the purpose of replication. Replication refers to the ability of other researchers to repeat a study and produce results similar to those found in the original. There are two types of replication—direct and conceptual. Direct replication occurs when a researcher repeats an existing study exactly as it was conducted originally. Conceptual replication occurs when a researcher repeats an existing study using different operationalizations of the same independent and/or dependent variables, or other modifications of the original procedures. Both forms of replication are important, but conceptual replication provides stronger support for a hypothetical cause-and-effect relationship among variables because consistent results across many conceptual replications reduces the likelihood that the results are simply a consequence of a single operational definition.

Research Design The strategy used to create equivalent groups and the ability of the researcher to manipulate an independent variable restricts the type of research design that can be employed. Specifically, experimental methodology can be divided into two categories, true experiments and quasi experiments. True experiments are characterized by (1) random assignment and (2) manipulation of the independent variable. In contrast, quasi experiments possess only one of these characteristics, which in most cases is manipulation of the independent variable. Three distinct true experimental designs and at least ten quasi-experimental designs have been identified. These basic designs can be combined or modified to produce a large number of possible research designs that can be used to test a broad range of cause-and-effect explanations.

Research Setting In addition to design issues, researchers must also select a research setting. There are two settings for research—laboratory and field. A laboratory setting refers to research conducted in a dedicated scientific laboratory; a field setting refers to any location other than the laboratory. Field settings are typically less controlled than laboratory settings, but they make up for this deficit by affording researchers an opportunity to study phenomena in a context that is similar to, if not the same as, the environments in which the phenomena occur naturally.

Realism and Impact Another consideration when designing and conducting an experiment is realism. Realism is the extent to which an experiment stimulates or reflects various aspects of the phenomenon under investigation. There are two types of realism—mundane and experimental. Mundane realism is the extent to which a phenomenon is studied in an environment similar to the one in which it occurs naturally. In contrast, experimental realism is the extent to which real psychological processes occur within the context of the study, regardless of the artificiality of the experimental setting or procedures. As a general rule, researchers tend to maximize experimental realism even if doing so minimizes mundane realism, because the presence of extraneous variables that may accompany mundane realism reduces the capacity of researchers to derive a causal inference from the study. Although the distinction between mundane and experimental realism does map onto the distinction between laboratory and field settings, these issues are distinct and should be treated as such.

Related to the issue of realism is impact. Impact refers to the intensity of the process or phenomenon elicited in
a study. High-impact studies typically involve situations designed to maximize the experience or expression of the phenomenon. Low-impact studies, which are sometimes called judgment studies, typically involve assessing or recording simulations of a process or phenomenon in an “as if” manner. Low-impact studies are typically less desirable than high-impact studies because participants asked to simulate a process may respond in a manner that is unrepresentative of how they would respond if the process or phenomenon in question were actually occurring. The choice of impact level is often determined by the phenomenon under investigation, resources available to the researcher, and ethical considerations.

Validity Of major concern to scientists is the validity of different research designs. In this connection, validity refers to the extent to which a design is free of confounds (i.e., flaws) that serve as alternative explanations for the proposed causal effects of the independent variable on the dependent variable. Confounds can be divided into two types—threats to internal validity and threats to external validity. Internal validity refers to the absence of alternative explanations for the causal relationship between the independent and dependent variables. External validity refers to the extent to which the results of an experiment can be generalized to other operationalizations of the independent or dependent variable, other populations, or other settings. Both types of validity are important, but researchers tend to focus on internal validity because a study with low internal validity is not interpretable. When research results are not interpretable, the generalizability of the results is irrelevant.

Eight threats to internal validity and four threats to external validity have been identified. The eight threats to internal validity are:

- history (changes on the dependent variable due to events other than the independent variable),
- maturation (changes on the dependent variable due to time-dependent changes in characteristics of the participants during a study),
- testing (changes on the dependent variable due to the effects of measuring the dependent variable at an earlier point in time),
- instrumentation (changes on the dependent variable due to changes in the calibration or accuracy of measurement instruments),
- statistical regression (changes on the dependent variable due to the assignment of participants to different groups based on extreme characteristics or abilities),
- selection (changes on the dependent variable due to differential selection of participants for possessing certain characteristics or abilities),
- mortality (changes on the dependent variable due to differential loss of participants from different groups in a study), and
- interactions between two or more threats to internal validity.

The four threats to external validity are: (1) interaction of testing and the independent variable (pretesting can alter participants’ sensitivity or responsiveness to the independent variable, which can render responses from pretested participants unrepresentative of non-pretested participants); (2) interaction of selection and the independent variable (participants selected for a study because they possess certain characteristics may respond to different levels of the independent variable in a manner that is unrepresentative of participants who do not possess those characteristics); (3) reactive arrangement (the arrangement of the experimental context may produce effects that do not generalize to nonexperimental situations, particularly when participants’ responses have been altered during a study because they know they are being observed); and (4) multiple-treatment interference (multiple levels of the independent variable applied to the same participant may produce interference among the different levels and produce effects that would not occur if each level were used independently).

ETHICS IN EXPERIMENTAL METHODS
Following a series of unethical studies in the first half of the twentieth century, the scientific community along with the Nuremberg war tribunal developed a code of ethics for scientific research. Succinctly, this code requires that research participants freely consent to participate, be fully informed of the purpose and potential risks associated with participation, and be afforded the right to discontinue participation for any reason at any time. Similarly, the researcher must strive to minimize risks to participants, protect them from harm insofar as possible, and be fully qualified to conduct the research with honesty and integrity. This code and other more stringent ethical principles developed by individual branches of social science are enforced by Internal Review Boards (IRBs). IRBs are institutional panels of experts and community volunteers that review the potential risks to participants of studies proposed by researchers. IRBs carefully examine the procedure and materials that are to be used in a study to ensure that the researcher is doing everything possible to protect participants from undue harm. Consequently, the goal of IRBs is to balance the benefits of acquiring scientific knowledge with protecting the rights of research participants.
One point of concern for IRBs is informed consent, which typically entails a document that outlines the rights of research participants as well as the potential risks and benefits associated with the study for which they have volunteered. It is necessary for participants to freely consent and fully understand these benefits and risks in order for a study to meet the ethical requirements set forth by the scientific community. However, informed consent is somewhat problematic in research that involves some form of deception. In such cases, it may be unclear whether enough information has been supplied at the outset for participants to fully understand the risks of participation. Similarly, informed consent is problematic when working with vulnerable populations such as young children or individuals with poor mental health who cannot understand or communicate informed consent, prisoners who may feel compelled to participate in research, individuals who do not speak the language in which the informed consent document is written, and people with poor physical health. Also, research on nonhuman animals poses problems with consent and raises additional ethical responsibilities. In such research, it is important to provide humane and ethical treatment, and to take steps to minimize discomfort, illness, stress, and privation.

The culmination of a study, and the resolution of a researcher’s ethical obligations, is the debriefing—the full disclosure to participants by the researcher of the purpose and procedures of a study, including any deceptive elements. In addition to disclosure, another purpose of a debriefing is to assess and rectify any adverse effects that may have occurred during the study. Adverse effects include stress, pain, threats to self-esteem or identity, and the like. It is the researcher’s responsibility to provide affected participants with appropriate remedies or treatment options, or to otherwise undo any harm done.

**EXPERIMENTS, CONTROLLED**

In the social sciences, a controlled experiment is any study in which at least one variable—a presumed cause—is manipulated, the units of observation (individuals, groups, or organizations) are randomly assigned to levels of the manipulated variable, and there is at least one control condition. Experiments can be contrasted with quasi-experiments, in which the putative cause is manipulated but there is either no randomization or no control condition, and with nonexperiments, in which there is no manipulation, randomization, or control condition. Although quasi- and nonexperimental studies are useful, and sometimes necessary, in social science research, the information they provide is of limited value when the goal of the research is to detect causal relations. Controlled experiments, by virtue of manipulation, randomization, and control conditions, are the social scientist’s best option for detecting causal relations.

The power of controlled experiments lies in their capacity for achieving control and isolation of the causal variable in a presumed cause-effect relation. When variability in the presumed cause is controlled by the experimenter through manipulation, the only plausible direction of influence between the variables is from cause to effect. The context within which the putative cause varies also must be controlled. Control in this sense involves attending to other variables that covary with the presumed cause or are present in the research context that might contribute to variability in the outcome. Isolation concerns the potential co-occurrence of a causal variable and other variables. To the extent that the presumed cause is confounded with other variables, inferences about its influence will be ambiguous or even incorrect. Control over variability in the presumed cause and isolation of it from other potential causes are necessary for unequivocal inferences of causal influence.

Although random assignment to levels of the manipulated variables also figures into control over the putative cause, its primary role in causal inference is isolation. If the units of observation are randomly assigned to conditions, then, apart from the manipulation, the conditions are presumed to be probabilistically equivalent. Their equivalence is only probabilistic because there is some likelihood that, apart from the manipulation, the conditions differ. This probability is accounted for in the construction of statistical tests allowing for apparent difference between levels of the putative cause to be attributed either to the manipulation or to nonequivalence. By convention, these tests ensure that an apparent difference attributable to nonequivalence is attributed to the manipulation no more than 5 percent of the time. Social scientists often report the precise probability, or $p$-value, of the
statistical test comparing conditions in an experiment, with values less than .05 indicating statistical significance.

Although random assignment is essential for isolating a presumed cause from other causal influences, it does not rule out alternative explanations for differences on the presumed effect attributable to the manipulation itself. Strategically designed control conditions address this type of alternative explanation. The prototypical control condition is the placebo condition in experiments on the causal effects of medications. The goal of these experiments is to isolate the effects of active ingredients in the medication from other effects, such as those that accrue from simply receiving medication or attention from a physician. By comparing outcomes for individuals who take a medication with those for individuals who believe they are taking the medication but in fact receive none of the active ingredients, researchers can distinguish effects attributable to the active ingredients from the effects of receiving any medication or seeing a physician. Because a control condition of this sort keeps research participants “blind” to condition, it also rules out the possibility that participants’ assumptions about the effects of the manipulation explain differences in the outcome.

Controlled experiments often include more than one causal variable, with each having two or more levels. In the typical experiment with multiple causal variables, the variables are “fully crossed” to create a factorial design. In factorial designs, units of observation are randomly assigned to all combinations of levels of the causal variables, with the total number of conditions equal to the product of the number of levels of the causal variables. Such designs often are referred to in terms of the number of levels of each causal variable. The simplest factorial design is the $2 \times 2$ (“two-by-two”), which comprises two causal variables, each with two levels. Such designs allow for the detection of causal effects of the individual variables as well as interaction effects, in which the causal effect of one of the variables varies across levels of the other.

Despite their appeal as a means of detecting causal relations, controlled experiments are not always appropriate in social science research. In some instances, particularly in the early stages of a program of research, social scientists are interested in simply capturing the natural co-occurrence of variables without concern for causality. Controlled experiments are unsuitable for such purposes. In other instances, social scientists are interested in causal relations but cannot, for practical or ethical reasons, design controlled experiments to study them. These limitations might preclude manipulation, random assignment, or the assignment of some individuals or groups to a control condition. For example, some characteristics of individuals, groups, and organizations either cannot be manipulated at all, or cannot be manipulated ethically in a manner that creates variability on the causal variable of interest. Furthermore, it is not always possible to randomly assign units of observation to condition, as, for instance, in the case of an intervention administered by teachers to students who are in a condition because they were assigned to that teacher’s class according to school or district policy. Finally, in the case of studies of treatments that have the potential to save lives that otherwise could not be saved, it is unethical to withhold the treatment from research participants, thereby precluding inclusion of a no-treatment or placebo control condition. Thus, although controlled experiments are ideal for detecting causal relations, they are not always appropriate or feasible. Because of this, social scientists typically view controlled experiments as only one of numerous approaches to studying associations between variables.

EXPERIMENTS, HUMAN

In the social sciences, human experimentation involves the study of human behavior under controlled conditions using scientific methods. The practice of using human beings as experimental subjects was borrowed from the medical sciences in the late nineteenth century by those who later were credited with helping to lay the foundation for modern psychology. Separately, William James (1842–1910) in the United States and Wilhelm Wundt (1832–1920) in Germany established the first experimental psychology laboratories in 1875. These pioneers conducted simple experiments involving human perception,
Experiments, Human

memory, and cognition. Their success with the experimental approach revolutionized the study of human behavior and significantly influenced the development of all of the social sciences throughout the twentieth century. Today human experiments are widely accepted as an important research tool not only in psychology, but also in sociology, economics, and other specialized fields.

Experiments using human subjects can assume a wide variety of designs and employ simple to complex procedures. The most basic form of a human experiment involves two sets of subjects—a treatment group and a control group. Subjects in the treatment group are exposed to some form of stimulus (experience) that is under controlled manipulation by the experimenter. Subjects in the control group do not receive the stimulus, but are like the treatment group in all other respects. The resulting effect of the stimulus on the treatment group is then measured and compared to the control group. For example, a researcher interested in the effect of background noise on students’ reading comprehension may design an experiment where students in a treatment group are asked to read a passage from a book while a radio is played nearby; meanwhile, students in a control group are asked to read the same passage, but in a noiseless environment. Both the treatment group and control group students then take a test on the assigned reading and the test results are quantitatively compared and contrasted. Researchers can manipulate various elements of an experiment to test a variety of hypotheses. In this example, the researcher could examine how the type of noise independently affects reading comprehension by alternating music with talk, or even white noise, while holding all of the other elements the same. Likewise, the effects of age or gender could be explored by selecting human subjects from differing populations. Thus, even a simply designed experiment can be a powerful research tool. Beginning with this basic approach, social scientists over the past century developed sophisticated techniques and procedures to study a vast array of human behavior. However, the widespread practice of human experimentation also caused social scientists to carefully examine their own motives and ethics.

ETHICAL CONSIDERATIONS

Just as the modern history of using human beings as experimental subjects in biomedical research is littered with controversy and scandal, the same is true in the social sciences. In the decades following World War II a number of human experiments made headline news due to the ethical questions that they raised. The most noteworthy of these include Stanley Milgram’s “obedience to authority” study in 1963 and the Philip Zimbardo’s “imprisonment” study in 1973.

In Milgram’s study an experimenter instructed human subjects to administer increasingly severe electrical shocks to another, unseen person. Unknown to the subjects, the shocks were fictitious and the other person was collaborating with the experimenter. In response to the “shocks” the collaborator would scream, leading the subject to believe that the shocks were real. Milgram conducted the study to explore how people respond to authority figures when directed to perform harmful acts against other human beings. Likewise, Zimbardo too was interested in studying the human reaction to authority, but did so in a simulated prison context. Zimbardo assigned “guard” and “prisoner” roles to subjects and then proceeded to observe their behavior as subjects were instructed to undertake various activities common to life inside a U.S. prison. The experiment took place in a college laboratory especially redesigned, complete with cells, to simulate a prison environment. During the course of the experiment the confrontations between the guards and the prisoners became so intense that a prisoner rebellion ensued and a breakout was attempted. Given these events, concern for the physical and mental safety of the subjects caused the experiment to be terminated prior to its planned conclusion.

Although no one was seriously harmed in either study, the Milgram and Zimbardo experiments are often cited along with notorious cases in biomedical research, such as the decades-long “Tuskegee syphilis study” in which, to serve as a control group, poor African Americans infected with syphilis were denied medical treatment; the fallout from this experiment led to regulatory oversight of human subjects research in the United States and in other nations. In 1974 the U.S. Congress passed the National Research Act, which established a National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. This body’s 1979 “Belmont Report” (named after the conference center where the commission met) set forth the three basic ethical and moral principles that serve as the foundation for the regulatory rules that now govern all human experiments conducted at institutions receiving funds from the U.S. federal government. These three principles are respect, beneficence, and justice.

The principle of respect includes the tenet that experimental researchers should honor all human subjects’ right to personal dignity, freedom of choice, and privacy. The beneficence principle stipulates that researchers conducting human experiments have a societal obligation to maximize the benefits and minimize the costs associated with their work. Finally, the principle of justice concerns the obligation of researchers to treat all human subjects with fairness.
The Belmont Report proposed that each of the three basic principles have equal moral weight and recognized that in some situations they may conflict with each other. Therefore, the commission recommended that experiments using human subjects should be objectively evaluated and judged based on their own merits relative to all three principles. This perspective is clearly reflected in the prevailing federal regulations that shape the way human experiments are conducted today.

REGULATORY ISSUES
The primary regulations that govern the practice of human experiments in the United States are included in the Federal Policy for the Protection of Human Subjects (Code of Federal Regulations Title 45–Part 46). This policy is often referred to as the “Common Rule” because it has been adopted by sixteen federal departments and agencies that conduct or financially support research using human subjects. The Common Rule is explicitly based on the Belmont Report’s three ethical and moral principles.

Under the principle of respect, the Common Rule regulations require researchers to explicitly obtain each human subject’s informed consent before proceeding with any experiment. All potential benefits and harms to the human subject must be clearly explained and each subject must have the option of quitting the experiment at any time. The regulations also require researchers to maintain the privacy of their human subjects by not divulging the names or any personally identifying information collected during the course of an experiment.

To uphold the principle of beneficence, the Common Rule regulations require researchers to ensure that all human experiments possess a favorable ratio of potential benefits to potential risks. Furthermore, researchers must demonstrate that they are capable of properly conducting human experiments and that they have procedures in place to handle the apparent risks.

Federal regulations derived from the principle of justice include the requirement that human subjects be selected in a manner such that the risks and benefits of participation are equitably shared across participants. The justice principle is also the foundation for a variety of rules that ensure that vulnerable populations are not exploited by researchers conducting human experiments. Thus, numerous regulations safeguard prisoners, children, the mentally impaired, and other special groups.

Enforcement of the Common Rule regulations is a decentralized process, and primary oversight is at the local level. The policy mandates the establishment of institutional review boards (IRBs, also known as internal review boards) at all institutions, including universities and research centers, that conduct human experiments and receive federal dollars. An IRB is composed of professional researchers and administrators who screen proposals for research involving human subjects. Researchers wishing to conduct human experiments, or any other research activity that includes the observation of human behavior or the collection of data from human beings, must receive approval from their institution’s IRB before proceeding. Local IRBs are charged with enforcing the federal policies and protecting the rights of human subjects. Institutions have a powerful incentive to maintain a diligent IRB because the code allows for the withdrawal of all federal funding from institutions found in violation of the Common Rule.

The influence of the Common Rule and the institutionalization of local IRBs is a topic of debate among many American social scientists. Most agree that enforcement of the Common Rule does protect human subjects from overly risky experimental practices, but some argue that the federal code stifles research activities that inherently carry low levels of risk. For example, researchers proposing to conduct a marketing survey or an oral history project must receive either approval or an exemption from their local IRB, even though the personal risk of participating in either of these practices is negligible. An IRB review requires paperwork and time commitments that may discourage some researchers from pursuing a project. Additionally, the decentralized approach of enforcing the Common Rule results in an uneven application of the regulations. Projects that receive approval from one local IRB may not be approved by another IRB, causing difficulties for research teams composed of members from different institutions. Even though these hurdles exist, the number of empirical research studies using human subjects, as recorded in the academic literature, continues to increase each year with little evidence to suggest that the regulations have significantly affected the quantity of research conducted.

EXPERIMENTS, SHOCK
The term shock experiment brings to mind ghastly images. Most of these experiments use animal participants and a level of shock that often is more startling than painful (like the shock we sometimes receive when exiting a car). Some shock experiments use human participants, but rather than shocking them, these experiments usually only lead people to believe they will receive a shock or will be delivering shocks to others. Even though these experiments carry a negative connotation, the conclusions drawn from some of them have had a significant impact on psychology and other disciplines. The three main areas in which shock experiments have been used are learning, emotion, and obedience.

LEARNING
Shock experiments are used to study learning (i.e., a change in behavior due to experience). Classical conditioning is a form of learning involving associations. Most humans and animals learn a behavior after being exposed to sequentially presented stimuli. For example, a researcher might expose a rat to a light and then deliver an electrical shock to its feet. Eventually, the rat will learn that the light is a signal for the shock; turning it on will cause the rat to behave in the same way it would if shocked. The rat has learned to associate shock with the light. Although this example is relevant, most shock experiments investigate the more complex aspects of learning.

EMOTION
Shock experiments are used to investigate emotions such as anger and moods such as depression. In a well-known set of experiments in the 1960s and 1970s, Martin Seligman (b. 1942) and colleagues used electrical shocks to study personal control and depression. In one experiment, Seligman delivered inescapable shocks to a group of dogs. Later, these dogs (and a control group of dogs not exposed to the inescapable shocks) were placed in a cage split in half by a barrier that could be jumped to reach the other side. When Seligman electrified one side of the floor, the dogs previously exposed to inescapable shocks were less likely than the control-group dogs to jump to the safe side of the cage. The dogs that failed to jump to safety had learned to be helpless and exhibited depressive-like symptoms.

This phenomenon was labeled learned helplessness. Experiments revealed that some humans also exhibit depressive-like symptoms when in uncontrollable situations (e.g., inescapable noise). The identification of learned helplessness was important in revealing the thought processes involved in depression. Researchers continue to study learned helplessness in humans and animals, and electrical shocks are routinely used in these experiments with animals (most often rats).

OBEEDIENCE
Stanley Milgram (1933–1984) made shock experiments infamous in the 1960s, leading people to equate psychology with shocking people. Milgram was interested in the conditions that foster obedience and disobedience. Obedience is the carrying out of a command given by a person of authority. Milgram's interest in obedience was sparked partly by the Nazi atrocities, which spurred him to investigate to what extent ordinary people would harm an innocent person when ordered to.

Milgram studied 1,000 participants in several experiments. His basic experiment involved the use of a shock machine, an authority figure, and forty male participants who believed that the experiment was investigating punishment and memory. Participants were told that they would be required to deliver electrical shocks to a person in another room whenever he answered a question incorrectly, and they received sample shocks of 45 volts to convince them that the shock machine was real. The participant was told to increase the intensity of the shocks by 15 volts with each incorrect answer by flipping a switch on the machine, which had settings from 15 to 450 volts and ominous labels below the voltage readings (e.g., “slight shock,” “moderate shock,” “strong shock,” “very strong shock”). Although the participants were convinced that they were delivering painful shocks, in fact, the person in the other room was a confederate (i.e., an accomplice) who did not actually receive shocks. The authority figure, a stern man in a lab coat, ordered the participants to shock the confederate whenever an incorrect answer
was given. At several points, the confederate complained of pain and asked to be released, eventually shouting “My heart’s starting to bother me now. Get me out of here, please. My heart’s starting to bother me. I refuse to go on. Let me out.”

Milgram was interested in determining the level at which participants would discontinue their obedience by refusing to deliver shocks. Of the participants in the experiment described here, 65 percent obeyed the order to deliver shocks up to 450 volts. These individuals obeyed even after the confederate stopped answering (presumably because he was incapacitated). This high level of obedience stunned Milgram and the world.

Milgram’s experiments are classics in psychology. His findings are provocative because they revealed the capacity ordinary people have for obeying destructive orders. Milgram’s use of deception, however, was considered unethical by many people. The participants believed they were inflicting harm, and many exhibited signs of extreme stress (e.g., trembling, sweating, biting of the lips, and stuttering). Critics contended that permanent harm was imposed on participants. Milgram countered critics by contacting many former participants; only 1 percent reported regret at having been in the experiment. Furthermore, a psychiatrist interviewed forty participants and found that none of them had suffered permanent harm.

The ethics of Milgram’s experiments are debatable. Nonetheless, his and other controversial experiments (e.g., the Tuskegee study) prompted changes in research standards. In 1974 the National Research Act became law. This act, along with guidelines written by the American Psychological Association, required that human and animal research be reviewed by Institutional Review Boards (IRBs), which ensure that no undue harm is done to humans or animals, and that humans voluntarily consent to participate. Although deception is allowed, the deception permitted by IRBs does not typically involve physical harm, but rather the mental discomfort that comes from being deceived.

Although it is certainly doubtful that an IRB would approve an experiment such as Milgram’s, shock experiments are routinely conducted on animals (and to a lesser extent on humans), but the level of shock typically used in these experiments is far from debilitating. In questioning the ethics of any experiment, one should consider the amount of pain inflicted and the knowledge to be gained before making definitive conclusions about the value of shock experiments.

EXPLOITATION

In Keywords (1976), his foundational book on historical semantics, Raymond Williams includes discussion of the word exploitation because it illustrates the general problem of how important historical and social processes occur within language. On the one hand, exploitation is a key word in the English language because it is tightly bound up with the problems to which it refers; and on the other, it is an exemplar of what Williams calls “transfer”—that is, how new kinds of relationships and new ways of seeing relationships appear in languages, in this case by transferring a word from one semantic usage or historical context to another.

There are three broad senses in which exploitation is currently deployed. The first is as a modern form of industrial or commercial land use (or mineral extraction) derived probably from its Latin root meaning an “arrangement” or “explanation.” This particular use came into English in the nineteenth century, often in regard to the commercial exploitation of the colonies, building upon the fourteenth- and fifteenth-century meanings of exploit as “successful progress” or “taking advantage.” The meaning of exploitation as making use of resource opportunities for social advancement—the exploration of oil resources in Nigeria, for example—remains commonplace.

A second meaning is a generic sense of unjustness or oppression, referring to a potentially wide range of social relations across time and space (e.g., exploitation of men by women, workers by capitalists, slaves by slave owners, low castes by high castes, serfs by feudal overlords). The range of opinion as to what constitutes exploitation is substantial, ranging from the instrumental treatment of humans (Buchanan 1985)—a Kantian view—to coerced activity (Moore 1973) to psychological harm (Hill 1994). The analytical content is of less concern than its moral standing and the moral force of the reasoning (i.e., whether and how the state should prohibit exploitative transactions or refuse to enforce such agreements).
Exploitation

The third meaning, which is the focus of this entry, is explicitly analytical in the sense that it purports to provide a theoretical and conceptual ground on which the claim—A exploits B when A takes unfair advantage of B—can be assessed. In Old French, the feudal meaning of the word *exploitation*—a seizure of products from the land for which a tenant had failed to pay homage—provides a foretaste of its modern use in the mid-nineteenth century, as its reference is increasing the industrial capitalist system. In philosophical terms, one can say that social science seeks to understand the truth conditions under which such a claim can be made of a particular social setting. It is in this sense a term of social critique—exploitation refers to people, not resources—and it is very much rooted in classical political economy. Whether drawing from Adam Smith, David Ricardo, or Karl Marx, exploitation is inseparable from class structure and the operations of class-based power. Each of this trio has a moral core to his argument, but the forms of measurement differ radically among them. Although exploitation can also be accommodated within neoclassical economics or Weberian social theory, it is within the Marxist tradition that the analysis and theorization has received its fullest elaboration.

The notion of an unjust benefit from the labor of others that emerged by physiocratic thinking was formalized by Smith and Ricardo in the distinction between productive and unproductive labor and the question of the shares in the distribution of wealth. Neither Smith nor Ricardo was especially concerned with the moral class atlas of income distribution unless it concerned the landlord class. Conversely, the English anticapitalist and socialist writers of the 1830s (e.g., Thomas Hodgskin, Robert Owen) formulated the first Ricardo-inspired theory of exploitation that turned on the appropriation of wealth by the owners of capital and employers as an unjust deduction from the product of labor. In France, the Saint-Simonians and Pierre-Joseph Proudhon came to similar conclusions through an analysis of property ownership. Few of these public intellectuals agreed on the justness of the rewards due to property (rent, interest, profit), but they held in common the idea that, *contra* Simonde de Sismondi, exploitation was less a regrettable accident than central to the operations of the modern economic system.

From these tentative beginnings, the theorization of exploitation matured in the work of Marx and the notion of surplus appropriation and the labor theory of value. Marx's account identifies a fundamental contradiction at the heart of capitalism—a contradiction between two great classes (workers and owners of capital) that is fundamentally an exploitative relation shaped by the appropriation of surplus. Unlike feudalism, in which surplus appropriation is transparent (in the forms of taxes and levies made by landowners and lords backed by the power of the Church and Crown), surplus value is obscured in the capitalist labor process. Marx argued that labor is the only source of value, and value is the embodiment of a quantum of socially necessary labor. It is the difference between the sale of a worker's labor power and the amount of labor necessary to reproduce it that is the source of surplus value. The means by which capital extracts this surplus value under capitalism—through the working day, labor intensification, enhancing labor productivity—coupled to the changing relations between variable and constant capital determine, in Marx's view, the extent, degree, and forms of exploitation. In the first volume of *Capital* Marx identifies the origins of surplus value in the organization of production (the so-called "social relations of production"). In volume 2 Marx explains how exploitation affects the circulation of capital, and in volume 3 he traces the division of the total product of exploitation among its beneficiaries and the contradiction so created. In Marxist theory, two kinds of material interests—interests securing material welfare and interests enhancing economic power—are linked through exploitation (exploiters simultaneously obtain greater economic welfare and greater economic power by retaining control over the social allocation of surplus through investments). Members of a class, in short, hold a common set of interests and therefore have common interests with respect to the process of exploitation.

In the wake of Marx's work, the central debates over exploitation have turned on (1) whether the labor theory of value is a necessary condition for any truth claim about exploitation, (2) whether exploitation can be made congruent with complex forms of class differentiation associated with modern industrial society, and (3) whether there are non-Marxist accounts of exploitation. In neoclassical economics, for example, exploitation is a type of market failure due to the existence of monopoly or monopsony. In more developed versions of this organizational view, exploitation can be rooted in extramarket forces, for example free riding or asymmetric information (the so-called "principal agent problem"). There is a heterodox side to conventional marginalist approaches to economics—most readily seen in the work of Joan Robinson (1933) and the Cambridge school—in which exploitation is understood as wage payments less than the marginal product of labor (see also Brewer 1987).

More structural accounts of exploitation from a liberal vantage point are found in the ideas of Henry George (2006) and John Maynard Keynes (1936), for whom landowners or rentier classes (nonworking owners of financial wealth) produce not exploitation in the Marxist sense, but exploitation as waste and inefficiency due to "special interests."
In the Marxist tradition there has been in general an abandonment of the labor theory of value—away from the view of Jon Elster that “workers are exploited if they work longer hours than the number of hours employed in the goods they consume” (Elster 1986, p. 121)—toward John Roemer’s notion that a group is exploited if it has “some conditionally feasible alternative under which its members would be better off” (Roemer 1986, p. 136). Perhaps the central figure in developing these arguments is Erik Olin Wright (1985, 1989), who developed a theory to account for the contradictory class location of the “middle classes”—that they are simultaneously exploiters and exploited. Building on the work of Roemer, Wright distinguishes four types of assets, the unequal control or ownership of which constitute four distinct forms of exploitation: labor power assets (feudal exploitation), capital assets (capitalist exploitation), organization assets (statist exploitation), and skill assets (socialist exploitation). While pure modes of production can be identified with single forms of exploitation, “actually existing capitalism” all consist of all four, opening up the possibility of the simultaneous operation of exploiter/exploitee relations (for example, managers are capitalistically exploited but organizational exploiters).

A long line of Marx-inspired theorizing has, of course, attempted to grasp exploitative relations between countries. This is the heart of theories of imperialism (Lenin 1916) as the coercive extraction of surplus through colonial states (Fanon 1967), through unequal exchange (Arrighi and Pearce 1972), or through the imperial operation of transnational banks and multilateral development institutions (the World Bank and the International Monetary Fund). The so-called “antiglobalization movement” (focusing especially on institutions such as the World Trade Organization) and “sweatshop movements” (focusing on transnational firms such as Nike) are contemporary exemplars of a politics of exploitation linking advanced capitalist state and transnational companies with the poverty and immiseration of the global south against a backdrop of neoliberalism and free trade (Harvey 2005; Starr 2005).

EXPORT PENETRATION
In a world of increased international interdependence, the entry and capture of an increasing share of export markets (or expansion of export market share) plays an important role in a nation’s industrial and overall economic growth. The expansion of export market share by a single product
or a group of products is generally referred to in the literature as export penetration. The success or failure in export penetration depends on a host of domestic factors, such as production costs where the product is produced, and foreign factors, such as the degree of competition in foreign markets where the product is sold.

Export-oriented industries or countries can use their level of success in export penetration as a performance indicator. Researchers calculate export penetration ratio(s) to measure the degree of export penetration of industries or countries. In this way they can evaluate their export market performance over time and across industries and countries. Depending on the availability of data, export penetration ratios are measured in many ways. The most commonly used method measures the market share captured by the product(s) in the trading partner’s import market. For example, if in a given year the value of U.S. agricultural exports to Canada is $100 billion (in U.S. dollars) and the value of Canada’s total agricultural imports from all its trading partners is $200 billion, the export penetration ratio for U.S. agricultural exports to Canada is 0.5 (or 50%). This ratio indicates that U.S. agricultural exports to Canada accounted for half of the Canadian market for agricultural imports. Some researchers use other measures such as the proportion (or percentage) of the output exported as a measure of export penetration ratio. An increase in the ratio indicates a successful capture of a larger market share by the exporter, and hence indicates satisfactory market performance.

Export penetration has helped increase both internationalization of economic activity and international integration of economies that contribute to the process of globalization. Export promotion has become a popular development strategy among several developed and developing countries in the recent past. As a result, many countries have carried out economic liberalization and deregulation policies in support of export promotion. Export penetration is of vital importance for the growth of export-oriented industries and the success of these strategies. However, economic liberalization and deregulation policies in developed and developing countries have generated both positive and negative effects on export penetration. On the one hand, they have made export penetration easier by removing barriers to international trade. On the other hand, the removal of barriers has opened up markets for increased competition among exporters in external markets, making it difficult (or easy) for exporters to compete depending on their comparative advantages in international trade. Researchers have linked the level of productivity directly to the degree of export penetration.

EXPORT PROMOTION

Export promotion policies reflect the interest of national governments to stimulate exports. Subsidies, tax exceptions, and special credit lines are the main instruments used to promote exports. The regulatory aspects of export promotion changed significantly in the late twentieth century. In the past export promotion activities were not substantially regulated, but increasingly since the creation of the World Trade Organization (WTO) in 1995 some export promotion activities have been identified as trade-distorting practices. The WTO has devised rules that allow countries that have been affected by the export promotion practices of their trading partners to use the WTO’s dispute-settlement procedure and in some cases retaliate.

Export promotion is sometimes seen as a complementary development strategy to import protection. While import protection usually allows infant industry to develop, export promotion allows access to external markets. Foreign demand is often required by the limited size of domestic markets and the need to achieve economies of scale, essential in many productive activities. In a 1984 article Paul Krugman argued that, under increasing returns to scale, import protection may act as a form of export promotion, because in this case protection would allow considerable gains in terms of productivity that would enhance the possibilities of exporting. However, in policy circles export promotion or export oriented industrialization (EOI) is seen more often as an alternative development strategy to import substitution industrialization (ISI).

There are two main interpretations about the advantages of export promotion. One has a laissez-faire bias,
while the other emphasizes the role of state intervention in promoting exports. Conventional wisdom suggests that an emphasis on exports forces integration into world markets and a more efficient allocation of resources, because external markets impose discipline by eliminating uncompetitive firms. In other words, exports affect positively the supply side of the economy. This view, espoused by Ian Little, Tibor Scitovsky, and Maurice Scott in 1970 and by Bela Balassa in 1971, was influential within the World Bank and the International Monetary Fund (IMF), and it shaped the Structural Adjustment Programs (SAPs) of the 1980s and influenced the liberalization strategy of the Washington Consensus. The studies by Anne O. Krueger and Jagdish Bhagwati, both in 1978, and by Demetris Papageorgiou, Michael Michaely, and Armeane M. Choksi in 1991 suggested that ISI policies generally did not produce sustainable increases in income per capita and that export promotion policies were more appropriate for achieving that goal. Export promotion, in this view, is associated with liberalization and market reforms.

Defenders of outward orientation tended to argue that EOI was behind the successful experience of the Asian countries. The World Bank's 1993 report The East Asian Miracle supported the view that East Asian economies' successful export performance resulted from the implementation of market-friendly policies. Several authors have shown the limitations of the World Bank position. Ajit Singh, in his 1995 paper “The Causes of Fast Economic Growth in East Asia,” argued that despite the strong export orientation, the East Asian economies were not fully integrated with the world economy and that ISI was an integral part of the East Asian strategy in the 1950s and the 1960s. The equalization of export orientation with free trade is also misleading. In her 2001 The Rise of “the Rest,” Alice H. Amsden argued that the state intervened heavily in the economy of successful least developed countries (LDCs). In the East Asian economies, protection, conditional on export promotion, allowed import-substituting infant industries to become internationally competitive export-oriented industries. More generally Francisco Rodríguez and Dani Rodrik, in an influential 2000 article published in the National Bureau of Economic Research (NBER) Macroeconomics Annual, showed that the evidence for a negative relationship between trade barriers and economic growth is weak at best.

The alternative view emphasizes the role of exports in expanding demand, in contrast with the conventional view that emphasizes supply effects associated with improved resource allocation. Higher demand provides an outlet for producers in economies with relatively limited domestic markets. The foreign trade multiplier, developed by Roy Harrod, indicates that net exports have a positive effect on the level of activity. Nicholas Kaldor argued that higher levels of exports lead to strengthening productivity, lowering unit costs, which would then positively impact exports. This positive effect of exports on productivity, known as the Verdoorn effect, reduced unit costs and led to further increases in export in a cumulative process of economic development formalized by Robert Dixon and Anthony Thirlwall in their 1975 paper. The notion of a circular and cumulative process of growth led by exports harks back to Adam Smith's vent for surplus principle.

The alternative view also differs from conventional wisdom in that it does not equate export promotion with free market policies. Raúl Prebisch, in a United Nations 1964 report, emphasized the importance of export promotion and access to the markets of developed countries to promote industrialization in LDCs. More importantly, to avoid recurrent balance of payments crises, LDCs should diversify their exports rather than rely on commodity exports. Prebisch argued that LDCs should replace traditional commodity exports with manufactures or semi-manufactures exports. Industrial policy would have a central role in promoting export diversification. State selective intervention, by providing support for research and development (R&D), imposing restrictions on licensing and royalties, and coordinating with and among private sector agents, is central to increase and diversify exports.

Several authors have also emphasized the limitations of the EOI strategy. Robert A. Blecker, in his 1999 essay “The Diminishing Returns to Export-Led Growth,” noted that export-led growth is a strategy that cannot be pursued by all countries at the same time. Export promotion requires that at the other end there is an importer of last resort, in other words, a country with the international reserve currency and an incredible appetite for imports. Also the integration of China into the world economy and its relatively low labor costs suggest that countries with higher labor costs would find it increasingly difficult to pursue export oriented development strategies. The global imbalances that result from simultaneous export promotion efforts around the globe are a threat to the stability of the global economy.

**BIBLIOGRAPHY**

Exports originated with the start of communication and have been present since prehistoric times. According to the historian Peter Watson, people began bartering goods and services 150,000 years ago, as part of long-distance commerce. There is also evidence of exchange of obsidian and flint during the Stone Age, while materials used for making jewelry were exported to Egypt since 3,000 BCE. Long-range export routes first appeared in the third millennium BCE, when Sumerians in Mesopotamia traded with the Harappan civilization, and continued with the Phoenicians, who traveled across the Mediterranean Sea and established trade colonies. From the beginning of the Greek civilization until the fall of the Roman Empire in the fifth century, exports from the Far East to Europe flourished. However, the fall of the Roman Empire and the Dark Ages led to a disruption of the main export networks. Subsequently, noteworthy landmarks included the contribution of Vasco da Gama to the trade of spices and the dominance of Holland, Portugal, and Britain in the sixteenth, seventeenth, and eighteenth centuries, respectively. Exports continued to expand in the nineteenth and twentieth centuries, particularly after World War II with the creation of international institutions, and in the twenty-first century with the telecommunications revolution.

The reduction of barriers to international trade has been crucial for exports. With technology improvements—container ships, telecommunication networks, and the Internet—it is easy for producers in one country to reach consumers in another and to export their products quickly. Governments have also recognized the importance of free trade and have reduced export (and import) quotas and tariffs, including in the context of multilateral agreements (the European Union and the North American Free Trade Agreement). Moreover, the World Trade Organization was created to facilitate free trade by mandating mutual most favored nation trading status between all members. Finally, to help exporters find markets for their products, countries have set up export promotion agencies as an integral part of their export strategies.

The payments and receipts associated with exports take place in major international currencies (U.S. dollar, euro, and yen) and are recorded in the current account of the balance of payments. The latter is usually kept in terms of the international currency in which the country’s majority of trade transactions are conducted. The current account balance is calculated as the difference between exports and imports of goods and services. When the value of receipts from external transactions exceeds (falls short of) the one of payments, the country runs a current account surplus (deficit). Several different models have been developed to study export developments and analyze the effects of export policies. The Ricardian model—
developed during the first quarter of the nineteenth century by economists David Ricardo, James Mill, and Robert Torrens—postulates that countries specialize in producing and exporting what they produce best. The Heckscher-Ohlin-Samuelson (H-O-S) model incorporates the neoclassical price mechanism and argues that the pattern of exports (and trade) is determined by differences in factor endowments (labor, capital, and know-how). It predicts that countries will export (or import) goods that make intensive use of locally abundant (or scarce) factors. Finally, the gravity model postulates that exports and imports are determined by the distance between countries and the interaction of the countries’ economic sizes.

Macroeconomic policy could have significant influence on export developments, since the demand for a country’s exports is a function of each good’s price in foreign currency. Thus, macroeconomic policies that affect the exchange rate weigh on exports. For example, tight monetary and expansionary fiscal policy both lead to a higher real interest rate, which makes domestic assets attractive to foreign investors; as foreigners demand domestic assets, the real value of the domestic currency rises sharply. Because the domestic currency is strong, exports become more expensive and thus could fall sharply.

One measure to gauge the importance of exports is their ratio to gross domestic product, known as the index of openness. Countries with high value of the index are considered relatively open, while the opposite is the case for relatively closed economies. In line with globalization trends, the average (worldwide) index of openness increased from 30 percent in 1980–1990 to 40 percent in the beginning of the twenty-first century. The most open economies have values of the index over 100 percent: Hong Kong (190% in 2004), followed by Luxemburg (146%), and Malaysia (121%). On the other hand, relatively closed economies are characterized by low openness indexes: Burkina Faso (8.6%), Burundi (8.9%), and Rwanda (10.3%).

According to the World Trade Organization, in 2005 total exports reached $12.6 trillion, comprising $10.2 trillion of merchandise exports and $2.4 trillion exports of commercial services. Exports of goods and services each increased by an annual average of 10 percent over the 2000–2005 period. Europe dominates world exports, accounting for 43 percent of the total in 2005; Asia follows with 28 percent, and North America with 15 percent. At the individual country level, in 2005 the five largest exporters of merchandise goods were: Germany (9.3% of world exports), the United States (8.7%), China (7.3%), Japan (5.7%), and France (4.4%). The leading exporters of services were: the United States (14.7% of world exports), United Kingdom (7.8%), Germany (6.2%), France (4.8%), and Japan (4.5%).

Turning to the commodity composition, manufacturing exports have led overall growth, increasing by an average of 6.5 percent annually during 1990–2005 compared with 3.5 percent for agricultural products and 3.5 percent for fuels and mining products. In 2005 merchandise exports comprised: $7,312 billion manufacturing, $1,748 billion fuels and mining products, and $852 billion agricultural products. As for services, transportation accounted for $570 billion, travel for $685 billion, and other services for $1,160 billion.

Globalization trends and improvements in telecommunications will support strong export dynamics over the medium and long term. However, due attention needs to be paid to maximize the benefits for economic growth of all countries. In this connection, although recent efforts on trade liberalization are encouraging, some calls for protectionist policies raise concerns. There is no doubt that continued trade liberalization will create more opportunities and raise the potential for faster global growth.

**EXPOSURE THERAPY**

**SEE** Psychotherapy.

**EXPROPRIATION**

**SEE** Confiscation.
**EXTERNACITY**

The term *externality* originated in economics, but it is now widely used in the social sciences and the popular press. In economics it is defined as: (1) benefits or costs of an economic activity that spill over to a third party (e.g., pollution is a negative spillover, while a positive spillover would occur when neighborhood property values are enhanced by the restoration of a rundown house); (2) an incidental effect produced by economic activities, but that does not enter the cost or benefit decisions of either buyer or seller; (3) uncompensated benefits (costs) to others as a result of an action taken by an economic unit; (4) any cost or benefit generated by one agent in either production or consumption activities that also affects another agent in the economy.

The economist Ronald Coase (1960) suggests that externalities are reciprocal, and that it is a case of selective perception to say that A harms B rather than B harms A. Hence, the idea that pollution is a spillover and an incidental outcome seems misplaced. Take the production of steel for example. The recipe for steel includes iron ore, coke, labor, and blast furnaces. Also necessary is a place to put the waste, either on the land or in the atmosphere as a pollutant, as well as a warehouse to store the steel until it is to be used. One of these items is no more incidental than another, and any industrial engineer would know all the ingredients. Is the cost of the waste storage accounted for by the market? How is the cost of labor accounted for? The steel producer would not pay for labor if there were not a prohibition against slavery—that is, if people did not own their labor power. If a producer does not own a necessary ingredient to its production, it must be bought in the market. If it is already owned, the owner will consider its *opportunity cost*, or what it could be sold to others for. This is true of iron ore and labor as much as for a place to put the waste. An owner of the atmosphere, whether it be a steel company or the general public, may submit a bid to the company, and if the bid does not exceed its value in use for producing steel, the company will use it. This is how any resource input is accounted for.

Does the action to use an owned resource taken by the steel company produce an uncompensated cost (or benefit) for others? None could be expected if the resource is owned by the steel company. Thus, if the steel company uses its land for a blast furnace, farmers could not expect to be compensated for the land not being used for agriculture. If a farmer has a better use for the land, then a bid can be made for the resource. The issue then boils down to who owns the resource. To own is to deny opportunities to others who need the resource; to own is to coerce and visit uncompensated lost opportunities on non-owners; and to own is to be the recipient of bids, not the payer of compensation to others. The ability of an owner to withhold what others need is the source of all income.

In a world of scarcity, any production or consumption activity affects another agent in the economy. The policy issue concerns who is the buyer and who is the seller of any contested economic opportunity. In the words of Coase, externalities are reciprocal. If A owns, it harms B, but if B owns, it harms A. Externalities are ubiquitous. They are the stuff of human interdependence. The term *externality* might be usefully replaced by *interdependence*, with nothing inherent in the term implying who should own or who should do without if they cannot make an attractive bid to the owner.

What about transaction costs? Given resource ownership, there may be buyers who are willing to meet the reservation price of seller-owners. Their potential bids may nevertheless be overcome by transaction costs and therefore rejected by the owners. The opportunity for a mutually beneficial trade may be lost. The most common example of transaction costs defeating a potential bid occurs in the case of high exclusion cost goods—those goods which if they exist for one person are available to all. This is sometimes called a “market failure,” and the inefficiency is often used to justify public taxation (or regulation), perhaps to buy out owners now using the atmosphere as a place to put waste. Those opposed to a role for government in such goods argue that governments may also fail to do the right thing (if that can be agreed on).

New interconnections in the economy are constantly being brought to people’s attention through new technology. No one worries whether a person has a particular opportunity to use or exchange an opportunity when that person does not have the ability to affect others. For example, no one worried about air rights before the Wright brothers. But then the issue arose as to who owned the air above the land. The interdependence between landowners and airlines became evident, and the question of ownership arose. Each wanted to be declared the owner, and to be entitled to compensation for any lost opportunity. The effect of each person’s use on the other is not incidental. Who should compensate whom is the issue. There is nothing in nature or economics that dictates the outcome of this contest. Cost is not independent of rights when the willingness to pay and the willingness to sell differ. Nations gave ownership to the airlines, and the landowners could not enjoin their use. If this had not been the case, the airline industry would have followed a different growth path. Later, as noise became as issue, regulations set a maximum for noise near airports. These regulations in effect gave ownership of some aspects of the atmosphere to those living near airports. Public choice of ownership, whether implemented by taxes, fees, or liability rules, determines what kind of world we live in.
Externality just points to the interconnections in any economy that might be better understood by referring to the connections as interdependencies, without any presumed policy conclusion. The interdependencies are sorted out by formal and informal institutions serving as property rights (ownership) and determining use or exchange opportunities (who has to buy what from whom). Changing ownership can change what is efficient.

FABIANISM

In January 1884, in London, about two dozen intellectuals created the Fabian Society. It has never had more than 80,000 members. Still, it has a universal significance in the history of social sciences that has been recognized even by its most outspoken critics.

The immediate antecedent of the creation of the society was a London visit of the New York philosopher Thomas Davidson. His twenty to thirty followers created the Fellowship of the New Life, which wanted to create a community of modest, unselfish people who with their way of life based on mutual love, tolerance, and wisdom would set an example for society. They hoped that the perfection of the individual would in turn lead to a perfection of the society. Some of the members, however, were also interested in direct political action. They created the Fabian Society, aimed at the gradual, democratic socialist transformation of British society. Being convinced of the inevitability of gradual change versus revolutionary turmoil, they adopted the name of the Roman general Fabius Cunctator (c. 280–203 BCE), who successfully delayed battles against the Carthagians in order to gain strength.

In its 2004–2005 program the society defined itself as “Britain’s leading left of centre think tank and political society committed to creating the political ideas and policy debates which can shape the future of progressive politics.”

The founders and early members included some of the Wittiest and brightest British minds of the time such as George Bernard Shaw, Beatrice and Sydney Webb, Edward Pease, Sydney Olivier, and Graham Wallas. The first Fabians were trying to pave the way toward the implementation of their ideas via the liberal and the conservative parties. In 1900 they participated in setting up the Labour Representation Committee, which was to become the Labour Party in 1906. They wanted to permeate society with their ideas; this aim was served by the publication of various small sized clearly worded tracts. Their first major publication, the Fabian Essays in Socialism of December 1889, gave them fame. In a year and a half the circulation reached 27,000, a number that previous socialist publications had never reached.

FABIAN POLITICAL VIEWS

The Fabians defined their political profile as socialist but clearly distanced themselves from Marxist socialism and socialists. They denied the necessity of a revolution for the transition from capitalism to socialism. The full realization of social and economic reforms (such as factory acts, housing acts, education acts) and legislation about the improvement of working conditions, together with a progressive taxation of capitalists’ income, would—they argued—smoothly lead to socialism. As pointed out by G. D. H. Cole in his 1932 essay on Fabianism in the Encyclopedia of the Social Sciences: “The economic problem was … presented as a question of the socialisation of monopoly incomes through social ownership of the monopolies…. [There] was no fundamental difference between land and capital or in the incomes derived from them. Both were mainly the results of differential monopoly” (i.e., the extra profit due to variety of land qualities and the potentiality of industrial production). According to the Fabian argument, the social control and fair distribution of income could guarantee the greatest happiness.
Fabianism

for the greatest number of people. Fabians assumed that all classes of society could be convinced of the efficiency and utility of their reform proposals. Even after the shocking experiences of various forms of labor unrest they did not adopt any class point of view.

Fabians were keen on the scientific approach to practical political problems. The Webbs initiated such large-scale empirical social studies as Life and Labour of the People in London (by Charles Booth, 17 volumes, 1902–1903) or The History of English Local Government (9 volumes, 1906–1929).

It was also four Fabians—the two Webbs, Graham Wallas, and George Bernard Shaw—who decided to create the London School of Economics on August 4, 1894. They believed that the systematic scholarly investigations of the functioning of their society needed a new, independent institution that also offered evening classes to workers who wanted to understand the limits and possibilities of political action.

Their impact was not limited to Britain. Eduard Bernstein in Germany wrote the introduction to the German edition of the Webbs’ Industrial Democracy. The same book was translated into Russian by Vladimir Lenin. What appealed to both Bernstein and Lenin was the Fabian call for the professional leadership of workers. Fabianism was echoed in Asia as well. Independent India’s first prime minister, Jawaharlal Nehru, developed an economic policy along Fabian lines. The founder of Pakistan, its first governor Muhammad Ali Jinnah, was a devoted member of the Fabian Society in the early 1930s. The first prime minister of Singapore, Lee Kuan Yew, also admits to having been influenced by Fabianism during his formative years.

INFLUENCE OF FABIAN IDEAS

A great number of people learned of Fabian ideas of social criticism from George Bernard Shaw’s plays, such as Pygmalion, Mrs. Warren’s Profession, and Major Barbara. When presenting examples of shocking dishonesty and hypocrisy of capitalist exploiters in his works before World War I, with his sharp, witty style, Shaw called for reforms along Fabian lines. In and after 1917 Shaw celebrated the program of the Bolshevik revolution as the incarnation of his ideas. Together with some other Fabians, such as H. G. Wells or later in the early 1930s, the Webbs, he believed in the Soviet model of the forceful implementation of a society without exploitation. This led to a split among the Fabians, as during the interwar period the majority of the members of the society were highly critical of the Soviet agenda. The splits were further aggravated by the conflicts over the evaluation of British imperialism. The Fabian founders hoped that the empire could create resources for easing social tensions: The imperial destiny would call for public expenditure to rear the imperial race. A number of second-generation Fabians were critical of British imperial policy.

Since 1918 when Sydney Webb drafted the Labour Party’s first major policy statement (New Social Order), Fabian policy has been adopted by the Labour Party and the Society has been affiliated with the party. Leading figures of the party, such as Ramsay MacDonald, Clement Attlee, Tony Benn, Harold Wilson, and even Tony Blair and Gordon Brown have been members of the Society.

In the first decade of the twenty-first century the Fabian Society had about 7,000 members. The Society continues to be affiliated with the Labour Party and its main focus is on fighting inequality and child poverty.

An overall evaluation of the Fabian achievement must recognize that Fabians contributed to reshaping the British party landscape, made socialism an acceptable option in British politics, and have substantially shaped the development of empirical social sciences. In the history of political thought they are perhaps the last to follow the enlightened tradition of believers in the possibility of, and acting for, the reasonable reconstruction of government and society on what they perceive as a scientific basis.

FACTOR ANALYSIS

Factor analysis is usually adopted in social scientific studies for the purposes of: (1) reducing the number of variables; and (2) detecting structure in the relationships between variables. The first is often referred to as common factor analysis, whereas the second is known as component analysis when both variables are operated as statistical techniques. While factor analysis expresses the underlying common factors for an entire group of variables, it also helps researchers differentiate these factors by grouping variables into different dimensions or factors, each of which is ideally uncorrelated with the others.

A major breakthrough in attitude measurement came with the development of factor analysis (1931) by psychologist L. L. Thurstone (1887–1955). Thurstone introduced multiple-factors theory, which identified seven distinct and primary mental abilities consisting of: verbal comprehension, word fluency, number facility, spatial visualization, associative memory, perceptual speed, and reasoning. This theory differed from the more general, less separated theories of intelligence that were prevalent at the time and was among the first to show that human beings can be intelligent in different areas. The concept of multiple factors slowly received validation from empirical studies and gradually replaced the unidimensional factor in social research.

In social science studies, researchers often face a large number of variables. Although it is a good idea for scientists to exhaust all the relevant variables in their research to provide thorough responses to research questions, such an approach makes a theory too complex to generalize to empirical applications. For example, a researcher may want to explain delinquent behaviors by exploring all relevant independent variables, such as illegal drug use, harsh parenting, school dropout, school failure, single-parent household, gang affiliation, parent-child bonding, smoking, alcohol use, and many other variables. With so many independent variables, it is difficult to provide a simplified model for a parsimonious explanation of delinquent behavior. A good theoretical explanation should achieve both consideration of completion and parsimony in its coverage of variables. Factor analysis reduces the number of variables to a smaller set of factors that facilitates our understanding of the social problem. It provides such functions to determine the “common factors” of these independent variables. Each of these common factors should be the best representative of certain independent variables, and every factor should be, theoretically, independent from the other factors. Researchers substitute these factors for the variables because the factors can explain a similar degree of variance on the dependent variable but are simpler in terms of the number of independent variables. In most cases, factors found in an analysis may not provide a complete description of the relevant independent variables, but these factors should be the most important factors, the best way of summarizing a body of data.

Factor analysis may use either correlations or covariances. The covariance \( \text{cov}_{ab} \) between two variables, \( a \) and \( b \), is their correlation times their two standard deviations: \( \text{cov}_{ab} = r_{ab} \cdot s_a \cdot s_b \), where \( r_{ab} \) is their correlation and \( s_a \) and \( s_b \) are their standard deviations. Any variable's covariance with itself is its variance—the square of its standard deviation. A correlation matrix can be thought of as a matrix of variances and covariances of a set of variables that have already been adjusted to a standard deviation of 1. Since a correlation or covariance matrix can be translated to one another easily, in many statistical books, authors may use either a correlation or covariance matrix or both to illustrate how factor scores are obtained.

The central theorem of factor analysis, in mathematical terms, is that we can partition a covariance matrix \( M \) into a common portion \( C \) that is explained by a set of factors, and a unique portion \( R \) that is unexplained by those factors. In matrix language, \( M = C + R \), which means that each entry in matrix \( M \) is the sum of the corresponding entries in matrices \( C \) and \( R \). The explained \( C \) can be further broken down into component matrices \( C_1, C_2, C_3, \ldots \) and \( C_x \), explained by individual factors. Each of these one-factor components \( C_x \) equals the “outer product” of a column of factor loading. A statistical program may rank several matrices \( C_x \) if it finds that there is more than one matrix with eigenvalues greater than 1. An eigenvalue is defined as the amount of variance explained by one more factor. Since a component analysis is adopted to summarize a set of data, it would not be meaningful to find another factor that explains less variance than is contained in one variable (eigenvalues of less than 1). Therefore, statistical programs often default this rule selecting factors.

Principal component analysis is commonly used in statistics for factor analysis and was introduced to achieve representation or summarization. It attempts to reduce \( p \) variables to a set of \( m \) linear functions of those variables that best describe and summarize the original \( p \). Some conditions need to be satisfied to have a set of \( m \) factors for the purpose of factor analysis. First, the \( m \) factors must be mutually uncorrelated. Second, any set of \( m \) factors should include the functions of a smaller set. Third, the squared weights defining each linear function must sum to 1, denoting the total variance explained. By using all \( p \), we get a perfect reconstruction of the original \( X \)-scores, while by using the first \( m \) (with the greatest eigenvalues), we get the best reconstruction possible for that value of \( m \) and the most simplified model for interpretation.
Statistical programs allow researchers to select how many factors will be chosen. Ideally, we want to identify a certain number of factors that would explain or represent all the relevant variables. However, the use of factor analysis is not just to find all the statistically “significant” factors; rather, those factors identified should be meaningful to the researchers and interpreted subjectively by them. If the factors generated are meaningless in terms of the compositions of variables, such a factor analysis is not useful. In general, researchers may use exploratory factor analysis to find statistically significant factors (eigenvalues > 1) if they do not have prior knowledge of what factors may be generated from a number of variables. Therefore, it is very common that two different researchers would have two sets of factors even though they used an identical dataset. It is not about who is right or wrong, but whether researchers can adopt a group of factors that lead to better interpretation of the data. If researchers have prior knowledge (e.g., theories) of those factors, they can limit the number of factors to be generated in statistical programs rather than allowing statistical programs to generate them. In other words, researchers determine if the proposed variables are grouped into factors as suggested by the theory.

Researchers may use the rotation of a factor-loading matrix to simplify structure in factor analysis. Consider a set of $p$ multiple regressions from $p$ observed variables, wherein each regression predicts one of the variables from all $m$ factors. The standardized coefficients in this set of regressions form a $p \times m$ matrix called the factor-loading matrix. We may replace the original factors with a set of linear functions of those factors for the same predictions as before, but with a different factor-loading matrix. In practice, this rotated matrix is expected to be used with simpler structures to better serve researchers’ subjective interpretations.

FACTORIES
The word factory refers to a building that has the primary function of housing physical production activities, often referred to as manufacturing. Although the origins of the word lie in manufactory, implying making by hand, the term factory can also refer to fully automated production systems. Locating manual craft production within a single building allows it to be changed in a number of ways. Firstly, factories allow production to expand a division of labor, splitting a single task into its components. Secondly, factories allow automation of production processes by creating opportunities for economies of scale. Thirdly, factories allow greater management control over production, enabling the emergence of a new social system, the factory system. The geography of the world economy has been shaped by three profound revolutions through which the contemporary factory system has evolved.

THE PRECONDITIONS FOR THE RISE OF A FACTORY SYSTEM
The idea of the factory emerged as a growing demand for mass-produced goods stimulated the growth of manufacturing industry. International trade in Europe began to take off from the fourteenth century; in the course of the fifteenth and sixteenth centuries, the Dutch economy grew rapidly and the Netherlands became a world power due to Amsterdam’s centrality to world trade. Trade provided a number of key preconditions for manufacturing’s growth. The linking of farmers to large-scale markets rewarded land-rich farmers able to increase agricultural productivity, releasing surplus labor power. Trade allowed particular localities to specialize in nonagricultural production for international markets while generating competitive pressures on craft producers, who had hitherto operated in local markets protected by town charters and guild systems. At the same time land-poor peasants sought alternative livelihoods and began to undertake small-scale production of domestic goods, such as textiles and pottery. Although some production was undertaken independently, merchants began to control this trade and soon effectively allocated output, in what is known as a putting-out system. Trade brought putting-out systems into competition with other producers, stimulating the coordinators—the merchants—to invest in more effective production methods.

THE EARLY FACTORY SYSTEM
These various factors created a situation ripe for attempts at significant productivity improvements through changes in the organization of production. An initial cost-reduction strategy brought formerly dispersed and contracted producers together in a single location, where merchants could more easily coordinate production with sales; this system is known as putting in. Moreover putting in allowed production to be organized into a series of mechanical tasks undertaken at a much lower cost, which, notes Adam Smith in The Wealth of Nations (1776),
allowed for innovation, notably the development of machinery to simplify and accelerate particular tasks.

Toward the end of the eighteenth century, Britain, which was protected by a patent system, underwent a huge mechanization of its craft industries. What can be regarded as the first modern factory was opened in 1769 by Richard Arkwright at Cromford, near Derby. This factory exploited a recently granted patent for a spinning frame, an invention that allowed one unskilled laborer to do the work formerly performed by twenty skilled weavers. Britain became the first world economy to harness external power sources through mechanization, thus providing the basis for the first factory revolution. The numbers of factories increased massively in this period, and the nature of British society evolved in response. On the basis of its improved productive capacity, Britain became a leading world power, supplanting the Netherlands.

In this period the negative features of the division of labor became most evident. The textiles industry experienced massive growth, creating rising demands for labor power. However, the demands for profits also drove the exploitation and immiserization of the labor force, and population pressures created by large-scale migration to industrialized regions led to a slum-based urbanization characterized by working poverty. Friedrich Engels cataloged the case of Manchester in great detail and at firsthand in *The Condition of the Working Class in England* (1845).

Factories provided a location in which workers had contact with others experiencing the same conditions as them, and this led to the realization that they could exercise power over capitalists through the collective withdrawal of their labor power. The early British factory system therefore drove the emergence of a politically mobilized and cohesive working class as well as the subsequent emergence of labor representation—namely, the trade union movement. Moreover through its impact on the thought of Engels and Karl Marx, the British factory system ultimately spawned the politics of communism.

THE SECOND FACTORY REVOLUTION: SCIENTIFIC MANUFACTURING

This first factory system depended on a particular contemporaneous British characteristic: a labor surplus resulting from workers having been driven out of agriculture by overseas competition and enclosure. This labor surplus drove down wage costs, which in turn encouraged minimal consideration for the human cost of production; child labor, long working days, and an absence of days off were all common features of the working environment. The labor surplus also reduced the incentive for ongoing investment in capital goods; it allowed for productivity to be raised by worsening employment conditions rather than through further mechanization.

However, this situation was specific to the British context. Other countries lacked a labor surplus; when Germany (after 1870) and the United States (during Reconstruction) began their own domestic industrialization, they faced a different calculus. An American labor power shortage and the ideological commitment of Kaiser Wilhelm to investing in the latest production techniques produced different factory arrangements in these newly industrializing economies. While British factories were limited in size by their surrounding communities and sunk investments into machinery and real estate, there were no such limits on the size of newly built American and German factories. Massive factories required massive investments and coordinated management, leading to the development of “trust” arrangements in America and Wilhelminian capitalism in Germany, in which profits were retained for future investment in large-scale mechanization.

This allowed a radical reconfiguration of the factory away from being the productive arm of a merchant capitalist to being a single element of a vertically integrated production process contained within a single firm. The potential for realizing further profits through resource efficiency achieved from more effectively managing vertical integration was recognized for the first time by Frederick Taylor in his 1911 opus *The Principles of Scientific Management*. Taylor’s system was perfected by Henry Ford for the production of the Model T car, the first truly mass-produced automobile, by ensuring that the Ford Company controlled the entire manufacturing process, down to owning fields of cattle from which interior leather was derived. In this system conflict with workers was avoided by paying a high wage, famously five dollars a day; at the same time workers were required to eschew alcohol, gambling, and immorality, prohibitions enforced by company inspection officers. Despite the high wages, this system further reduced the worker to being merely the instrument of the capitalist, a dehumanization process brought to its ultimate conclusion by the scientific automation underpinning the (Jewish) Holocaust.

POST-FORDIST FLEXIBLE PRODUCTION

The Fordist organizational system became increasingly important in Europe during the post–World War II (1939–1945) reconstruction period, although with checks and balances to guard against the dehumanizing effects of capitalist control. Social peace was provided through agreements between corporations, states, and unions representing the interests of workers. In Europe and North
America a great number of large, vertically integrated corporations emerged and came to dominate their national markets.

Scientific management was also introduced in Asia during the postwar period, most notably in Japan, but its principles were based on voluntary teamwork rather than top-down managerial control, enabling individual employees to exercise creativity. This system, termed Toyota-ism by some, had a number of advantages over Fordism. Geared to continuous product, process, and technique improvement, it allowed firms to serve increasingly sophisticated consumer markets. The social coordination it required led to a third revolution in the factory system from large vertically integrated factories to the “just-in-time” (JIT) production process, in which networks of factories owned by related corporations deliver goods to each other as they are required in their customers’ manufacturing processes. This innovation was complemented by novel developments in manufacturing, such as computer-controlled technologies allowing highly automated, flexible production systems with limited labor inputs.

Although the social contract underpinning JIT was not frequently adopted outside Asia, the competitive success of Japan in the 1980s encouraged many European and American corporations to reorient their production processes toward what has been called lean manufacturing. Falling labor costs in emerging economies alongside extreme specialization in the labor process has led many multinational companies to actively pursue separation of research, development, and design activities from manufacturing. This revolution of the factory system saw a change from the production line to more networked production organizations involving more extensive spatial and technical divisions of labor. Although individuals in the factory system exercised more creativity in tightly defined roles, the third revolution was characterized by increasing interdependence between corporate locations and a simultaneous separation of factories from their physical locations because of their involvement in global production networks, enabling increasing offshore manufacturing activities.

**FACTORY SYSTEM**

The factory system is a mode of capitalist production that emerged in the late eighteenth century as a result of England’s Industrial Revolution. Preindustrial England was largely organized around localized forms of production. Goods were produced on family-centered farms, and items such as yarn and other textiles were contracted for larger distribution or produced independently to be sold at a market. After technological innovations created the ability to produce textiles using waterpower, production became centralized in a single place: a factory owned in many cases by members of the former aristocratic class and staffed by workers who were paid a wage (see E. P. Thompson’s 1963 book, *The Making of the English Working Class*). While this mode of production began with the cotton and textile industries, it was the development of the steam engine that fully established the shift from craftspeople and localized production into production under the factory system.

There are several interconnected factors beyond technological innovation that created the factory system in England in its particular moment in history. One was the development of banking institutions, which were able to channel investments into the establishment of factories, and which were also able to facilitate economic exchange. Similarly, landowners were able to take advantage of the banking industry’s low interest rates to facilitate and finance the development of transit systems, created to move goods produced under this new system. At the same time, a rise in the British population not only increased demand for goods, but also created a large pool of laborers who would eventually work for a wage after the development of the factory system. Finally, social changes in Britain at the time both facilitated the training of upper-middle-class men who would administrate the factory system and also the development of British persons as free workers, as opposed to serfs, who could sell their labor power in exchange for a wage.
As such, the development of the factory system was central to the eventual entrenchment of capitalism on a world scale. It was this very shift in production and landownership, combined with the legal backing of free individuals who may enter into a state-sanctioned contractual relationship, that created what Karl Marx (1818–1883) would identify as the two classes in capitalist society: those who own the means of productions and those who own labor power, which they exchange for a wage in the marketplace. Although both workers and owners share the distinction of equality under the law, it was the old aristocrats who were able to develop the infrastructure and purchase the land to develop factories, and the old serfs who had nothing to sell and exchange but their capacity for labor. This system, whereby the owners of the factories could, through the labor process, transfer the value of the worker’s productivity into the value of a commodity, established the efficient yet exploitative mode of capitalist production that is still with us today.

The factory system was not only the foundation for the development of capitalism; it also radically shifted many aspects of social organization and daily life. Agricultural families were largely disenfranchised by this process, and in many cases were required to move to industrial centers in order to survive. They were thrust into the system of wage labor, fundamentally changing relationships between men and women. Whereas in preindustrial societies, all members of the family were involved in production work, the advent of the factory system created a gendered division of labor for middle- and working-class families, whereby men went to work for a wage and women were relegated to household work. In poor and nonwhite families, women worked for a wage outside the home in both formal and informal settings. Men were nearly always wagemakers, while women were either relegated to unpaid work to support the work of the men in their families or themselves worked for wages as a means of survival.

The link of the wage system to factory production created not only a different work process and a gendered division of labor, but also a new form of work. Whereas work under preindustrial forms of organization was often exploitative, particularly under systems of slavery and feudalism, the development of the factory system as a defining feature of capitalism created alienated work for the first time. Work is said to be alienated when the worker is in a relationship of production whereby he or she has no autonomy or control over what he or she is producing, where the goods being produced belong exclusively to the owner of the factory, and whereby this process makes the worker alien to himself or herself and his or her community. Marx, in his book Capital: A Critique of Political Economy (1867) argued that workers are alienated to the same extent that they are subject to livelihood exclusively through the wage labor market. This same process has created a social life whereby workers are more fundamentally tied to the workplace than to their homes in terms of livelihood and dependence. This process has also created levels of bureaucracy that divide labor into segmented, de-skilled tasks.

There has been tremendous resistance to the organization of work and social life under the factory system of production. Historically, that resistance has resulted in the abolition of child labor, the creation of the eight-hour workday, and various other labor laws regulating the extent to which owners of the means of production may exploit their workers. Moral arguments about whose labor is fair to exploit, and under which conditions that labor power may be extracted, have resulted in change. Many of the first nations to develop the factory system are now seeing a decline in factory production, as its mode of efficiency under capitalism seeks ever-cheaper ways to produce goods outside the limits of environmental and labor laws. These same nations have seen a shift from factory production to a service economy. However, the fundamental form of factory production, and the inherent link to exploitative relationships under capitalism, is as yet unaltered.

FAHRENHEIT 9/11

Fahrenheit 9/11 is a documentary-style film that explores both alleged causes and consequences of the terrorist attacks of September 11, 2001. The film is highly critical of Republican president George W. Bush and his administration, the U.S. Congress, and the mainstream media. It suggests that the Bush administration did not effectively pursue the perpetrators of the terrorist attacks because of close personal and financial ties to Saudi Arabia, and that Bush exploited the country’s unity in the wake of the attacks to promote a predetermined agenda to invade
Iraq. Among other things, the film highlights the differential costs of the Iraq war for rich and poor Americans, and it addresses the extent to which U.S. corporations have profited from the war, juxtaposing this with images of insolvent American communities, where young men and women are heavily recruited to fight the war. Fahrenheit 9/11 and its creator, Michael Moore, received lavish praise and harsh criticism, and both the film and filmmaker remain controversial subjects.

Michael Francis Moore, born April 23, 1954 in Michigan, is a filmmaker, author, and social commentator. Although most of his films are classified as documentaries, Moore’s style deviates from the neutral, observational style that typifies this genre. He refers to his films as “op-ed pieces,” and approaches his subject matter with a decidedly opinionated tone. He narrates his own films and employs humor, archival footage, movie clips, and sometimes strained, impromptu interviews to mock his adversaries and persuade audiences to adopt his liberal/left-wing perspective. Moore received an Academy Award for Bowling for Columbine (2002) and twice broke records for the highest-grossing documentary film (for Bowling for Columbine and Fahrenheit 9/11). His 2001 book Stupid White Men was a New York Times best-seller.

From a financial perspective, Fahrenheit 9/11 was a huge success. It was the top-rated U.S. film on its opening weekend (despite a limited theater release) and eventually became the highest-grossing documentary in history. It was also a critical success, earning Moore the prestigious Palme d’Or at the Cannes Film Festival. The political success of the film, however, was much less clear. A Pew Research Center poll suggested that Moore was “preaching to the choir.” Seventy-six percent of those who reported seeing the film disapproved of President Bush, and those who stated that they did not plan to see it were much more likely to be politically conservative (47%) than liberal (13%).

Given Moore’s confrontational style, it is not surprising that Fahrenheit 9/11 was met with strong opposition from conservatives, including attempts to prevent cinemas from showing the film and to block advertising for it. Many conservatives have attacked the ideas presented in the film as well as the filmmaker’s credibility. Perhaps more surprising was the opposition that Moore encountered from other liberals, such as Boston Globe columnist Ellen Goodman, journalism professor Robert Jensen, and former New York City mayor Ed Koch. Some observers have suggested that by provoking a backlash Fahrenheit 9/11 may have actually helped conservatives in the 2004 elections, although such claims are difficult to evaluate given the available data. What is clear is that Michael Moore has brought ideologically explicit messages to commercially successful documentary filmmaking, thereby inspiring other liberal documentaries including The Yes Men (2003) and The Corporation (2003), as well as numerous conservative parodies.

FALKLAND ISLANDS WAR

The Falkland Islands conflict took place between April 2 and June 20, 1982, and is of interest as an episode of non-superpower military crisis and war. The dispute centered upon the sovereignty of the South Atlantic archipelago, with both Britain and Argentina claiming first discovery and possession. The competing claims were bolstered on the British side by the islanders’ wish to remain a crown colony, and on the Argentinean side by the geographic proximity of the islands to the Argentinean mainland.

Prior to the conflict, successive British governments were prepared to reach a negotiated settlement of the sovereignty issue, but the islanders’ protests as to their Britishness and their opposition to living under Argentinean rule made a resolution difficult. British policy had therefore assumed a status quo character, involving slow-moving negotiations with Argentina in order to avoid matters coming to a head and to keep the issue off the British domestic political agenda. Little attempt was made to effectively defend the islands. A token garrison on land was supplemented by the lightly armed patrol vessel, HMS Endurance, at sea.
Two developments disturbed the status quo and led to fighting. First, a military junta headed by General Leopoldo Galtieri (1926–2003) came to power in Argentina. The junta recognized that capturing the islands would represent a huge domestic political coup. Secondly, cuts in the British defense budget meant that the *Endurance* was publicly slated for withdrawal from Falklands duty, seemingly indicating that British commitment to the islands had waned even further.

Consequently, when an adventurous scrap-metal merchant, Constantino Davidoff, landed on the island of South Georgia and raised the Argentinean flag on March 19, the junta took note of the desultory British response and launched a full-scale invasion. To the junta’s surprise, British Prime Minister Margaret Thatcher was not prepared to accept the fait accompli. A naval task force was quickly constituted to recapture the islands.

Given the 8,000-mile distance of the islands from the United Kingdom, the task force would take three weeks to reach its destination. The delay gave ample opportunity for diplomatic maneuvers, although the evidence is that Thatcher personally did not believe the matter could be resolved without the use of force. The United States, alarmed at the prospect of fighting between its European and Latin American allies, attempted to broker a compromise through the good offices of Secretary of State Alexander Haig. Haig, a protégé of Henry Kissinger, sought to repeat the latter’s “shuttle diplomacy,” but succeeded only in irritating Thatcher and misunderstanding the confusing signals emanating from the junta. His efforts came to naught.

When the fighting began it was episodic but fierce. The Argentinean air force, equipped with a limited number of French Super Etendard fighters and the dangerous Exocet missile, succeeded in sinking the British destroyer *Sheffield* on May 4, and HMS *Coventry* and the supply ship *Atlantic Conveyor* on May 25. The heaviest losses sustained by the British came on June 8, when the landing ships *Sir Galahad* and *Sir Tristram* were hit with the loss of two hundred men. However, the Argentineans failed in their primary mission of damaging the task force’s two aircraft carriers, *Hermes* and *Invincible*, upon which the success of the British effort depended. The losses the Argentinean forces sustained in trying were heavy. The single costliest action was the sinking by the British submarine *Conqueror* of the Argentinean heavy cruiser *General Belgrano* on May 4, with the loss of over three hundred men. This episode would later become controversial, as it emerged that a peace plan, sponsored by the government of Peru, was in the process of consideration by the junta when the decision to sink the *Belgrano*, which was sailing away from the British fleet and outside of its declared “exclusion zone,” was taken. Participants on the British side have always maintained that they were unaware of the plan and could not have accepted its terms in any case.

The fighting on land, beginning on May 21, pitted the British landing force against numerically superior but demoralized and poorly trained Argentinean defenders. The prospects for Argentinean military success had rested upon establishing superiority over the British naval force, and when this could not be achieved the Argentinean surrender, which came after several sharp engagements including the May 28 Battle of Goose Green, was inevitable.

In the years following the war, the British reinforced the islands through the so-called Fortress Falklands policy. Having failed to achieve the coup of recapturing the islands, the Argentinean junta fell shortly after the end of the conflict. The investment involved in the Fortress Falklands policy, including the influx of a sizable contingent of British troops, revitalized the islands’ economy and, ironically, led to greater trade with the Argentinean mainland. Diplomatic relations between Argentina and the United Kingdom were restored in 1990, and in August 2001 Prime Minister Tony Blair became the first British leader to visit Argentina since the war.

FALSE CONSCIOUSNESS

The concept of “false consciousness” is derived from the Marxist theory of social class. The concept refers to the systematic misrepresentation of dominant social relations in the consciousness of subordinate classes. Marx himself did not use the phrase “false consciousness,” but he paid extensive attention to the related concepts of ideology and commodity fetishism. Members of a subordinate class (e.g., workers, peasants, serfs) suffer from false consciousness in that their mental representations of the social relations around them systematically conceal or obscure the realities of subordination, exploitation, and domination those relations embody. Related concepts include mystification, ideology, and fetishism.
Marx offered an objective theory of class, based on an analysis of the objective features of the system of economic relations that form the social order. A person's social class is determined by his or her position within the system of property relations in a given economic society. People also have subjective characteristics, such as thoughts, mental frameworks, and identities. These mental constructs give a person a cognitive framework through which to understand his or her role in the world and the forces that govern his or her life. One's mental constructs, however, may not accurately reflect social reality. In a class-based society, there is an inherent conflict of material interests between privileged and subordinate groups. In such a society, Marx asserted, social mechanisms emerge that systematically create distortions, errors, and blind spots in the consciousness of the underclass. If these consciousness-shaping mechanisms did not exist, then the underclass, which is always a majority of the population, would quickly overthrow the system of their domination. So the institutions that shape the individual's thoughts, ideas, and frameworks develop in such a way as to generate false consciousness and ideology.

Marx's theory of ideology is presented in *The German Ideology* (1845), cowritten with Friedrich Engels. The term ideology refers to a system of ideas through which people understand their world. A central theoretical assertion in Marx's writings is the view that ideology and thought are dependent on the material circumstances in which a person lives. Material circumstances determine consciousness, rather than consciousness determining material reality: “The hand-mill gives you society with the feudal lord; the steam-mill society with the industrial capitalist” (Marx 1847). A system of ideology supports the advantage of the dominant class, according to Marxist theory. The concept of commodity fetishism is discussed in *Capital* (Marx 1867). Marx used this concept to refer to the pervasive and defining illusion that exists in a commodity society. A commodity is perceived solely in terms of its money equivalent (its price), rather than being understood as standing within a set of social relations of production. Thus, the labor of the operator of a shoe-sewing machine disappears, and only the money value of the shoes is visible. Marx believed that this is a socially important form of mystification. In other words, the market society obscures the relations of domination and exploitation on which it depends.

Twentieth-century Marxist thinkers have given more systematic attention to a Marxist theory of consciousness and ideology than Marx provided. Georg Lukács (1885–1971) was one of the first European philosophers to reflect seriously on Marx's philosophical ideas. Lukács introduced the concept of false consciousness into Marxist discourse (based on a brief reference by Engels) in relation to a dialectical theory of knowledge. A more sociological treatment of class consciousness was provided by Karl Mannheim (1893–1947) in his effort to formulate a “sociology of knowledge” in the 1930s. The sociology of knowledge attempts to provide a theoretical account of the relationship between knowledge systems and the social conditions within which they emerge; this provides a theoretical framework with which to understand the workings of a system of ideology. Mannheim supported the idea that the social position of the bourgeoisie and the proletariat deeply influence the forms of knowledge that they embody, and he argued that these forms of material bias lead to a systematic falsification of social reality.

Antonio Gramsci (1891–1937) significantly extended Marxist thinking about ideology and consciousness in the 1930s, giving ideology a more active role in politics and history than classical historical materialism. He argued that the proletariat has the ability to influence the terms of its consciousness, so that there is an extended struggle between the bourgeoisie and the proletariat over representations of the existing social reality. The bourgeoisie generally exercises “hegemony” over the terms of ideology through its control of the instruments of consciousness. The proletariat, however, can exert influence through its own cultural institutions. This perspective introduces a major change into the classical theory of ideology, in that it denies that the subordinate class is simply the passive tool of the dominant ideology. The French philosopher Louis Althusser (1918–1990) provided an influential perspective on the role of ideology in a class-based society in *Lenin and Philosophy* (1971). Generally characterized as offering a structuralist interpretation of Marxism, Althusser's writings on the role of ideology in the social system diverge from the interpretation offered in *The German Ideology*. Althusser took issue with the notion that ideology is a feature of consciousness. Instead, he referred to the set of institutions that produce and reproduce social states of knowledge as an “ideological state apparatus.” He also disputed the assumption that there is an external social reality independent from ideology, believing instead that all features of reality are expressed in language and are inseparable from the features of consciousness singled out as “ideological.”

FAMILY

It is said that families have always existed and that people have always formed families. However, conceptions of family can vary considerably. Until the 1970s, it was believed that the extended family had been a social institution since medieval times throughout the Western world. This family form consists of a married couple and the parents of one of them plus the couple’s children. However, Peter Laslett (1915–2001) and his Cambridge colleagues showed that although the extended family existed, it was not a social institution. This belief in the long history of the extended family can be understood to be a myth if one considers the high mortality rate during previous centuries, when many mothers and fathers died before their children became adults.

The term nuclear family refers to a family formed by a socially accepted marriage between a man and a woman who live together with their minor children. The anthropologist George Peter Murdock (1897–1985) coined the term in his book Social Structure (1949). Murdock assumed that almost all cultures have had this nucleus as their basic and preferred family form. Some cultures build upon the nuclear family, while others combine nuclear families. One type of nuclear family is an extended family that consists of at least three generations under the same roof. Another type of combined nuclear family is the polygamous family that, when polyandrous, consists of one woman married (socially) to at least two men. Polygyny is one man married (socially) to at least two women. Another variation would be group marriages consisting of at least two women married to at least two men, but this phenomenon has never been found anywhere as a social institution. Group marriages have certainly existed but only for short periods of a decade or so, and they have never been a society’s preferred living arrangement.

What is a family?
The term family is often presented in definite form, the family, a phrasing that indicates that there is only one kind of family. In Western culture at least, this might mean the nuclear family. However, this concept carries a kind of ideological code, which implies that the nuclear family is supposed to be the best and that the concept is reproduced over generations (see Smith 1993). The term family can also be connected to the entire range of relatives, especially close relatives.

Family can be considered from various levels. On a societal level, the law might define what a family is; this often means at least one parent and at least one minor child, where the parent is supposed to take care of the child. Another example is family responsibility, where an adult child is supposed to take care of elderly parents. Other persons can also be included—as in, for example, the Sami culture (previously known as Lapps) in Scandinavia, where many, but not all, relatives are counted as family members.

Another level on which family can be considered has to do with companies and other organizations. Some companies differentiate between who can be counted as family, depending upon the situation. For example, an employee may be granted an entire day of leave to attend a funeral for a close family member or relative, while the funeral of a more distant relative will not warrant any time off. Some organizations are considered “family friendly,” which may mean that they offer various benefits or discounts to families. Family in such cases usually includes only the nuclear family or a simple variation of it.

Daniel Little

FAMILIES, FEMALE-HEADED
SEE Female-Headed Families.

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 83
Family

If ordinary people are asked to name the members of their family, they will give a variety of answers, even when the person asked believes that the meaning of the term family is culturally determined. The number of family members can vary from none up to several hundred. Included as family members can be spouses, children, parents, uncles and aunts, grandparents, cousins, and so forth but also lovers, friends, and pets. Family members counted in this way can also include deceased persons. This way of looking at the meaning of family is dependent upon who is asked as well as the situation. For example, someone included in one person’s family might not include that person as a member of his or her own family. There are no clear and objective boundaries of what constitutes family when it comes to the individual’s definition of her or his family and who its members are.

If people are asked whom they consider to be included in possible constellations of families, they give a variety of answers. Some believe that a one-parent household is not a family, whereas others think it is a family. Some think that the parents have to be married, while others think that cohabiting couples can also be families. Some believe that same-gender couples cannot be counted as a family, while others have a different opinion. This variety of answers means that some individuals and some cultures are very inclusive when it comes to what to include as a family and some are very exclusive.

Sometimes the unit for the concept of family is limited to the household. That use occurs primarily in censuses and other demographic studies, but it also occurs among lay people. However, many households include members that no one else in the household would classify as members of their family. At the same time, there are many persons who fall outside the family when using household as equivalent to family. This was and is still the case in some parts of the world where households include servants and other employed persons (see Levin and Trost 1992).

FAMILY-RELATED MATTERS

There are a number of issues related to the term family and the concept of family. As mentioned above, marriage can be one of them. Poverty can cause couples to not marry, since societally it is costly to marry. In people’s minds, one should have a home when marrying; informal norms in many cultures say that without a roof, a bed, and some kitchen utensils, one cannot marry. Social surroundings are also important, since people often normatively expect a marriage ceremony to be combined with a party for relatives and also for friends and neighbors. Therefore nonmarital cohabitation based on poverty has been common in many parts of the world and remains common in some (Rodman 1966).

A new type of nonmarital cohabitation has developed as a social institution in most of the Western world. With the liberalization that came after World War II (1939–1945), the normative structure of “family formation” was reduced. Now nonmarital cohabitation has made marriage less common, to the point of disappearing in some countries. This movement has made nonmarital cohabitation a social institution in many cultures; it is a kind of cohabitation that is not at all connected to poverty. In many countries, particularly the Scandinavian countries, all or almost all couples live together in a nonmarital cohabitation relationship for years before marrying. The trend toward more nonmarital cohabitation has decreased the number of marriages, and both brides and grooms are on average much older now than in the past.

Another change in the way couples live together is referred to as living apart together (LAT). Such relationships consist of a married or nonmarried couple, with or without children, who each have a home and who visit each other, perceive themselves to be an intimate couple, and are so perceived by those in their social surroundings. These relationships have always existed in the Western world among, for example, writers and other artists. The difference between these earlier relationships and those of the early twenty-first century lies in part in the number and in part by the fact that LAT relationships constitute a new social institution. For example, in Sweden about 5 percent of the adult population lives in an LAT relationship (Trost and Levin 2000).

Such relationships could not have developed as a social institution had nonmarital cohabitation not become a social institution with the dissolution of the normative structure of the four elements of traditional social structure listed above. Had not the normative connection disappeared between the acts of marrying, moving in together, having sexual intercourse together, and the expectation of a child within about a year, LAT relationships would not have been possible. The social institution of nonmarital cohabitation is thus a prerequisite for the existence of LAT relationships.

Another issue connected to family is changes in divorce laws and divorce practice. Divorce has for many centuries been a social institution permitted in many cultures but prohibited in others. In the Western world, where the changes have been obvious, claims for more liberal divorce laws came at the end of the nineteenth century as a result of rapidly decreasing mortality rates. With such decreases, the idea of lifelong marriages slowly became obsolete, and divorce laws changed slowly in a more liberal direction. (The number of remarriages in many countries is now the same as in the middle of the nineteenth century. Previously the high mortality rate widowed many married women and men; many of these
widows and widowers remarried, while now most remarriages occur after one or both partners has divorced.)

During the nineteenth century the total fertility rate (TFR) was at a global level of above five (children per woman during her fertile lifespan). Partly as a result of improvements of contraceptive techniques and methods (better condoms and diaphragms, preventive pills, intrauterine devices) and propaganda, the TFR has decreased all over the world and even reached the low level of less than 1.5 (average number of children per woman) in many Western countries. These changes have caused few women to have more children than they want, but some will not have as many as they want. In the mid-twentieth century the average age of both parents at the birth of their children was much lower than now, which is one reason for the lower birthrates.

FAMILY FUNCTIONS

From a functionalist perspective, family has been seen as fulfilling a set of functions for the individual as well as for society. These functions, which have more and more come to be of historical interest, include the following.

The reproductive function means that women customarily give birth to children within a family union, and this makes society able to last in the long run. The early twenty-first century fertility rates in many less-developed countries will cause the population to increase, while in many developed countries the opposite will happen.

The socialization function refers to the upbringing of children into adulthood, a process that transfers habits and norms from one generation to another. Historically most socialization occurred within the family, but in the early twenty-first century much socialization is generated via school systems, media, and other sources.

The protective function gives the members of families protection against bad weather, keeps children in a safe environment, and leads family members to take care of the elderly and the sick. In most parts of the world this function has partly been taken over by society via social security and other social programs.

The sexual function means that sexual intercourse would occur within the marital union as part of family. In many parts of the world premarital and extramarital sex is taken care of through the use of prostitutes. Elsewhere the prohibition on premarital sex is no longer an issue with the liberalization of sex norms.

The religious function has to do with the exercise of religious activities, which are supposed to occur mainly within a family unit. In many parts of the world secularization has made this function less important.

The leisure time function is supposed to support family members during times when no work is needed. This function has in many parts of the world been subsumed by organizations outside the family.

Finally, the emotional or primary group function ideally takes care of the family members’ emotional needs. The term primary group was coined by the American sociologist Charles Horton Cooley (1864–1929) in 1909. The idea is that in small groups, of which family is one, the members can feel safe and secure not only physically but also emotionally. Reality, however, can be the opposite, with physical as well as emotional abuse and cruelty sometimes occurring in primary groups. Furthermore family as a primary group depends highly upon the definition one has of family. As mentioned above, membership in a family can vary greatly when considered from an individual perspective. In any case, many studies show that when a disaster strikes, the most important aid givers are family members and other relatives, who tend to be more helpful toward one another than any organization can be. This occurs in part because organizational helpers can seldom give the same emotional support that close relatives can.

For society to work, social order is needed; otherwise chaos will occur, and society will fall apart. When these family functions are in accordance with social norms and when family members, however defined, follow the informal norms, social order will remain relatively stable, assuming no opposing changes occur.

FAMILY, EXTENDED

Families are vitally important for patterning interpersonal behavior, roles, privileges, and obligations within society. These guidelines define how family relations are organized—how mates are selected; who marries whom; who lives together; who is the head of the family; which relatives are most important; and how children are to be reared and by whom. Throughout history, in most of the world, the extended family has been the most common household arrangement. Extended family refers to blood or kin connections that link successive generations through paternal or maternal lines of descent.

Definitions of the extended family incorporate other kin beyond the domestic group who do not belong to the nuclear family. When, for example, a married couple lives with the husband’s parents, or a grandparent shares a household, the family changes from a nuclear to an extended one. In his 1995 article “Patterns of Kinship and Residence,” Max E. Stanton offers clarity in defining an extended family as “an ongoing body with a geographical base and it transcends the lifetime of its members. The composition of the extended family with its nuclear families and independent single adults changes constantly, but the extended family itself continues with new leaders and new members as individuals depart or as the generations pass away” (p. 100).

An extended family can include a wide array of relationships. There can be genealogical connections between affinal relations (e.g., in-laws, adoptive or foster families, aunts/uncles), consanguineous relations (e.g., cousins, half-siblings), “fictive kin” (those perceived as extended family members, though they are not related by blood or law, e.g., godparents, best friends), or sundry other relations (e.g., stepparents or stepsiblings in blended/reconstituted families). To be succinct, Bernard Farber (2000) and Maria Schmeckle and Susan Sprecher (2004) support a definition of extended family as a vertical extension of a core nuclear family to include a third (e.g., grandparents) or even fourth generation.

An extended family is composed of one or more of four variants. First, the compound family is formed through the combination of nuclear families or parts of them, such as a polygynous household consisting of one man, his three wives, and their respective children. A second variant is a joint family and includes the parental couple, all unmarried children, and married sons with their wives and children in the same household. The head of household, in which authority is vested, is usually the eldest male. Third, a stem family exists when unmarried children and one married sibling, along with spouse and children, reside in the parental household (i.e., stem family) to ensure the continuity, while the other siblings establish their own households upon marriage. Typically, the eldest son is responsible for caring for his parents until they die, at which time he inherits the estate. This inheritance rule is called primogeniture; whereas inheritance by the youngest son is referred to as ultimogeniture. Finally, the modified extended family is one in which children marry out or migrate from the parental household upon marriage, but engage in common activities with parents and other kin on a regular basis.

Colleen Leahy Johnson (1998), Riley and Riley (1993), and Judith Stacey (1990) observe that extended family occurs in various, voluntary, and malleable contexts, making membership changeable and somewhat ambiguous. It is composed of three interlocking nuclear families: family of origin, family of procreation, and family of affinal relations (e.g., in-laws). The family of origin (or family of orientation) is the group into which a person is born. Most early childhood experiences and learning occur here. By contrast, the family of procreation is a group created when adults adhere to a socially recognized bond, such as marriage, and raise children. The affinal family derives from social connections acquired through family of procreation. Most people retain stable, though changing, status in one or more extended families throughout their lives.

BIBLIOGRAPHY
FAMILY, NUCLEAR

When people speak of “family,” they usually assume that what they mean is clear, yet the composition and structure of families around the world differ tremendously. Some equate family with a household, but this term is also ambiguous because it has been used to variously include all permanent members such as servants or to exclude unrelated relatives. Historically and cross-culturally, families are culturally determined interpretations of genetically and sexually grounded relationships. Further confusion, however, results for individuals involved in stable intimate relationships who consider themselves “family” but are either not willing (e.g., long term cohabiters), or unable (e.g., gay/lesbian relationships) to secure formal social recognition. Despite the complexities and challenges, however, two essential family structures have been posited; namely, nuclear family and extended family.

The basic family from which more complex forms arise is a nuclear family. At first glance, the definition of nuclear family appears to be straightforward. It is composed of parents and their children. A common, more nuanced definition specifies a nuclear family as two or more individuals affiliated by blood, marriage, or adoption. Regardless, a nuclear family is based on either consanguineous or blood relations, affinal relations (those related by marriage), or some combination thereof.

Genetic connections define consanguineous bonds (e.g., parent and child, or brother and sister), while relationships formed as a result of social convention (e.g., husband and wife, or in-laws) are affinally bonded. Affines also include all of a spouse’s own genetic relations. Thus, a woman’s brother is an affinal relation of her husband. Finally, the spouses of a person’s own consanguinal relatives are his or her affines.

A nuclear family is usually, but not necessarily, coresidential. The affinal tie between husband and wife forms the core of a nuclear family. Although spouses may enjoy relative autonomy and mobility in a nuclear structure, the dynamism intrinsic to such an arrangement can threaten conjugal bonds. Yet Martine Segalen (1986) and Azubike Uzoka (1979) illustrate in their works that the notion of an isolated nuclear family fragmented from other kin is a myth. The myth is embedded within and receives recognition from kin or the social group, as Marvin Sussman notes in his 1959 article “The Isolated Nuclear Family: Fact or Fiction.”

As comprehensive as definitions of family try to be, most focus on structural rather than functional aspects of the nuclear family. Whether a nuclear family is universal and necessary is debatable, as Arlene Skolnick (2003) and R. Smith (1968) have examined. Luis Lenero-Otero noted in his 1977 work Beyond the Nuclear Family Model that cross-cultural comparisons illuminate the ethnocentric problem of using structure as a basis for defining family. Thus, caution must be exercised in looking only at family structure—that is, the number of its members and their roles.

Families are ubiquitous in global society despite remarkable variability in form. The recognition of family heterogeneity is critical to understanding family from an international perspective. When a family includes other relatives beyond the nuclear core—consanguineous (e.g., grandparents) or affinal (e.g., aunts or uncles)—then an extended family exists.

BIBLIOGRAPHY

James J. Ponzetti Jr.
for ensuring the vital needs of food and shelter, the generation and maintenance of wealth, and the provision of care and other nonmaterial resources. Family functions, regardless of family structure, elicit similar behaviors and practices worldwide (Georgas et al. 2001).

Societies around the world rely on the family to perform certain functions. The basic functions of the family are to: (1) regulate sexual access and activity; (2) provide an orderly context for procreation; (3) nurture and socialize children; (4) ensure economic stability; and (5) ascribe social status. Families further impart affection, care, and adaptive functions. In short, family is considered the supporter of coupling, the source of nurturance and the elemental education of children, the link to the market place, the place of remediation that takes the wayward back, and the hospice where infirm and dependent members seek solace.

Family functions are accomplished in a number of different ways. Typically, marriage or some variant is socially approved as the appropriate outlet for sexual behavior. Families teach and reiterate that certain persons and conditions are more apt for sexual intimacy and affection than others. For example, there are taboos against incest and at certain times against intercourse, such as during menstruation or pregnancy. The regulation of sexual behavior is concerned with more than coitus, and covers such behaviors as hugging, kissing, and touching, as well as attitudes and values. These attitudes and values influence family reactions and cultural prescriptions to such practices as premarital and extramarital relationships (Widmer et al. 1998).

Families are the most widely approved context for bearing and rearing children. Procreation within a family garners social approval for parenthood, and delineates legitimate progeny. Children born outside a conjugal family are often stigmatized. Socialization is perhaps the most important function because it teaches the rules and expectations for behavior both within the family as well as in the society outside. In this respect the family is a miniature social system, with parents as the chief promoters and enforcers of social order. The outcome of the socialization process within the family is critically important for the larger society, which is based on regulation and the shared willingness of citizens to conform to social norms. Typically, family provides the security and support best suited for teaching children life skills, cultural values, and social responsibility. It is doubtful whether children could develop into mentally, physically, and socially healthy human beings without family.

The provision and management of sufficient financial resources is an essential function in order to facilitate the efficacy of other family functions. Families influence the social placement and life chances of individuals. Children generally assume the legal, religious, and political status of their family, whereas other roles are achieved through marriage, occupation, and education.

While some people prefer doing things alone, most need others who care for them, show affection, share joys and sorrows, and give support in times of need. Affection and emotional support are extremely important. A family can recognize changes and reorganize to adapt to its environment more rapidly than other groups. This adaptive function enables families to adjust to new demands and cope with change. Family life can exhibit openness to novel ways of living and thinking that have not developed in other spheres (Boulding 1981; Vincent 1966). While other institutions—religious, educational, political, and economic—may assist with these functions, the primary responsibility is relegated to family.

FAMILY PLANNING

Family planning is a term created in the mid-twentieth century to refer to the ability to control reproduction through access to contraception, abortion, and sterilization, in addition to access to information and education. Reproductive control allows a woman to determine when and whether she will have children. A woman’s ability to control the birth and spacing of her children has a direct impact on her educational, economic, and social opportunities. A woman’s enjoyment of heterosexual activity can be affected by the fear of becoming pregnant if she lacks information about, or access to, contraception and abortion.

Women have found ways to control their reproduction since the earliest days of recorded history. However,
these methods have not always been safe or effective. By 1900, every method of contraception (chemical, barrier, and natural means) had been invented, except for the anovulant method (the contraceptive pill and related methods of hormone regulation developed in the mid-twentieth century). Access to contraception was limited by law or by technological inferiority. In the United States, contraception and abortion were available through midwives, with a variety of contraceptive methods also available in the open market and through the advice of friends and family. With industrialization, urbanization, and the advent of new reproductive technologies, there was a shift away from women's ability to control their reproductive lives. By 1900, every state had criminalized abortion in most circumstances. In 1873 Congress passed the Act of the Suppression of Trade in and Circulation of, Obscene Literature and Articles of Immoral Use. The Comstock Law, as it was known, was named for the U.S. Postal agent, Anthony Comstock (1844–1915), who lobbied for the bill's passage. The law criminalized, among other things, the distribution of information and materials related to contraception and abortion through the U.S. mail. Legal or not, women often found means of controlling their reproduction, utilizing methods which were sometimes ineffective, dangerous, or in some cases deadly.

In the first decades of the twentieth century, social activists such as Margaret Sanger (1879–1966) and some members of the medical profession initiated a campaign for legalized contraception. Sanger was born into a large working-class family. She attended nursing school and later served as an obstetrical nurse in the Lower East Side of New York City. From her experiences as a nurse and as a child among eleven in her family of origin (her mother died at a young age as a result of multiple pregnancies within a short span of years), Sanger recognized the connection between the inability to regulate fertility and families' economic struggles as well as women's health. Later in life, Sanger would recall stories of women who begged her for information on how to avoid having more children or who fell ill and in some cases died as a result of a botched, illegal abortion.

Sanger's efforts to find information on safe, legal, and effective means to regulate women's fertility merged easily with her socialist perspective. In her socialist-feminist periodical, *The Woman Rebel*, Sanger first coined the term *birth control* in 1914. In the same year, she authored and published a pamphlet on methods of contraception, *Family Limitation*, based on her research on techniques and technologies of contraception available around the world. With her international research in hand, Sanger opened the first birth control clinic in the United States in 1916. One year later, she began to publish the periodical *Birth Control Review*. For more than a decade, the *Birth Control Review* provided readers with news and information on the fight for the legalization of contraception in the United States and overseas. In addition, Sanger traveled widely, organizing speaking tours and international conferences in an effort to coordinate the efforts of medical and social advocates for birth control. Thanks to the work of Sanger and others like her, by the mid-1930s various court rulings allowed contraception to be more widely available in the United States. Sanger's American Birth Control League (founded in 1921) merged with other advocacy groups to become the Planned Parenthood Federation of America in 1942.

Sanger's socialist roots in the birth control movement later evolved into a mainstream call for "planned parenthood"—the appropriate spacing of pregnancies to protect the health of mothers and children. The advent of the contraceptive pill in the United States in the 1960s led to a philosophical shift from birth control as a means of spacing pregnancies to a connection with the women's liberation movement—freeing women from a fear of pregnancy, allowing them to focus on their careers and shape their own destiny.

Sanger remains a controversial figure in American history. Because she founded Planned Parenthood, critics of abortion connect her work with the abortion services offered at Planned Parenthood clinics across the country. In vilifying its founder, they attempt to discredit her organization. However, Sanger repeatedly separated the provision of abortion from contraception. She believed that contraception was the best way to prevent abortion. A second controversy attached to Sanger is the assertion that she was racist. This is the result of her reliance on eugenics discourse in her speeches and articles in the 1920s and 1930s. Her support for the provision of contraception in the African American community and overseas (in China, for example) has fueled this argument. Eugenics, the science of selective breeding, has a long history. Before World War II (1939–1945), it was a term invoked by many in mainstream society, including politicians, physicians, and professors. Eugenists often called for the use (sometimes compulsory) of birth control (sterilization or contraception) to create a more stable, wealthier society by eliminating society's weakest elements. While some in the eugenics movement focused on health concerns (mental and physical problems), others concentrated on moral concerns (alcoholism and criminal behavior). At its most extreme, racial prejudice led Caucasian middle- and upper-class eugenicists to blame the burgeoning African American and immigrant communities for the nation's problems. An examination of Sanger's perspective on eugenics reveals that her focus was on health and economic improvement (smaller families have a higher standard of living) and was not specifically connected with race.
Contraception was still illegal in many states in the mid-twentieth century until the U.S. Supreme Court, in Griswold v. Connecticut, overturned a Connecticut law banning contraceptive use in 1965. The Court ruling legalized contraceptive access for all married persons, based on the right to privacy. In 1972, in Eisenstadt v. Baird, the Court expanded the right to access to contraceptives to include unmarried people—again, based on the right to privacy. The same right was invoked in the Roe v. Wade decision in 1973, when the U.S. Supreme Court legalized abortion in the first two trimesters of a pregnancy.

Within years of the Roe v. Wade ruling, reproductive rights were again limited by law. Between 1996 and 2004, 335 new state laws were created to restrict access to abortion services. Access to abortion was limited by income (the prohibition on Medicaid funding for abortions) and age (parental consent laws instituted at the state level). Other obstacles to access were also created in many states, such as waiting periods mandated between the time of the consultation and the procedure. By 2004 just 13 percent of U.S. counties had an abortion provider. This was the result of both restrictive state legislative action and violence (and the threat of violence) against clinics and clinic personnel.

In 1999 the U.S. Food and Drug Administration approved emergency contraceptives (the “morning-after pill”) for distribution with a prescription. Emergency contraception is a stronger dose of the standard contraceptive (anovulant) pill and is effective within seventy-two hours of unprotected intercourse. It prevents the implantation of a zygote (if there is one) on the uterine wall. As its name suggests, it is intended to prevent pregnancy if contraception fails or in the case of sexual assault. In 2006, following years of politically charged debate, the FDA approved emergency contraception for over-the-counter sales (without a prescription) for women over age eighteen.

A chemical abortifacient, RU-486 (named for the French pharmaceutical company Roussel-Uclaf, which patented it), was approved by the FDA in 2000. Women in Europe had used the drug since 1988. In U.S. tests, RU-486 was shown to be 92 percent effective in terminating pregnancies before the seventh week of gestation. The abortion pill was heralded as an alternative to surgical abortion, providing a more private experience—away from the clinics that are the focal point for abortion protesters.

Immediately following the Roe v. Wade decision, the religious and conservative right organized opposition to abortion. However, legislative lobbying and clinic protests against abortion have widened in scope to attacks on certain contraceptive methods. Those who believe life begins at conception see some methods—the contraceptive pill, the “morning-after pill,” and intrauterine devices—as abortifacients because they act to prevent pregnancy after a zygote has been created. Physicians and pharmacists opposed to abortion may refuse to prescribe, or fill prescriptions for, these forms of contraception. Pro-choice forces, on the other hand, hope to prevent abortion through increased access to contraception and comprehensive sex education. Because abortion is a debate of absolutes, pro-life and pro-choice forces will continue to be engaged in this issue.

FAMILY STRUCTURE

Among the most significant social changes that have occurred in recent decades are profound transformations in the structure of the American family. Prior to the last third of the twentieth century, most Americans lived in a family consisting of a husband and wife and their biological children. Both divorce and nonmarital childbearing were relatively rare (Popenoe 1996). Consequently, during the 1950s, over 80 percent of American children under
age eighteen were living with both biological parents, who were married to one another (Bumpass and Sweet 1989), and a large majority of adult men and women were married (Saluter and Lugaila 1998). Beginning in the 1960s, the structure of American families changed rapidly and dramatically (Wu and Wolfe 2001). The more prominent of these changes include much higher divorce rates (Cherlin 1992), more nonmarital births (Wu et al. 2001), the postponement of first marriage (Fields 2004), and an increase in nonmarital cohabitation (Bianchi and Casper 2000; Bumpass and Lu 2000). Understanding the factors leading to this dramatic transformation and the consequences of these changes is among the most significant issues faced by American society. In this entry, we explore recent data and research on family-structure issues and changes. Primary emphasis will be on the American family, but some international comparisons are provided.

**FAMILY-STRUCTURE CHANGES SINCE 1970**

For purposes of this entry, we use the definitions of *household* and *family* utilized by the U.S. Census Bureau. A *household* contains one or more people—everyone living in a *housing unit* makes up a household. There are two types of households: *family households* and *nonfamily households*. A family household has at least two members related by birth, marriage, or adoption. A family household is maintained by a married couple or by a man or women living with other relatives. A nonfamily household can be either a person living alone or a householder sharing a housing unit with nonrelatives, such as borders or roommates.

The data in Table 1 shows some of the major family-structure changes that occurred from 1970 to 2003. Most apparent are significant declines in the proportion of family households, especially married-couple families, and a corresponding increase in other family households (generally single parent) and nonfamily households. In 1970, 81.2 percent of all households in the United States were family households, and 86.9 percent of the family households included a married couple. By 2003, only 67.9 percent of all households were family households, and 75.8 percent of the family households included a married couple.

Table 1 also shows a significant increase in the median age at first marriage. For men, this increase was from 23.2 in 1970 to 27.1 in 2003, while for women, the increase was from 20.8 in 1970 to 25.3 in 2003. Further indication of the postponement of first marriage is apparent in looking at different age cohorts (data not shown). Of the cohort of individuals born from 1940 to 1944, 70 percent of the men and 79 percent of the women had been married before their twenty-fifth birthday. In comparison, of the cohort of individuals born from 1965 to 1969, only 40.6 percent of the men and 54.8 percent of the women had been married before their twenty-fifth birthday (Kreider 2005).

Other critical family-structure changes not shown in Table 1 that have occurred since 1970 include a substantial increase in both the proportion of births that occur...
outside of marriage and the number of cohabitating couples. About one-third of all births in the United States now occur out of marriage (McLanahan et al. 2001), while there has been a sevenfold increase in the number of cohabitating couples (to 5.5 million) since 1970 (Casper and Cohen 2000). The majority of these unmarried-partner households had partners of the opposite sex (4.9 million), but about one in nine (594,000) had partners of the same sex. Of these same-sex unmarried-partner households, 301,000 had male partners and 293,000 had female partners (Simmons and O’Connell 2003).

Tables 2 through 4 present information on current measures of family structure for the United States. Table 2 presents data on the marital history of American adults. The increased divorce rate is apparent by comparing those individuals who were in the fifty to fifty-nine age cohort with those who were seventy or more in 2001. About 40 percent of all persons aged fifty to fifty-nine had been divorced at least once, and about 30 percent had been married two or more times. In comparison, for persons seventy years old and older, only about 18 percent had been divorced and about 20 percent had been married two or more times.

<sup>a</sup> **Source:** Kreider and Fields 2005 (Based on 2001 data)<br>
<sup>b</sup> **Source:** Fields 2003 (Based on 2002 data)
Table 3 presents data on the family and living arrangements of children. In 2001, 61.2 percent of children in the United States from birth to age eighteen were living with both biological parents, who were married to one another. Another 9 percent were living with cohabiting parents or in a blended family. About one-fourth of the children were living with a single parent (usually the mother), and 4 percent were not living with either of their parents.

Finally, Table 4 shows extensive differences in family structure by race and ethnicity. Most significantly, only 30.9 percent of black households in the United States consist of a married-couple family, a proportion much smaller than for either whites or Hispanics. Hispanics, in contrast, have a much higher proportion of family households and a much lower proportion of nonfamily households than whites or blacks.

Patterns of U.S. family-structure change show some similarities to changes occurring in other economically advanced societies, but there are important differences. For example, the percentage of births occurring out of marriage is greater in Scandinavia, the United Kingdom, and France than in the United States. However, these countries have lower child-poverty rates and fewer children living in single-parent households because most unwed mothers are in long-term cohabitating partnerships (Kiernan 2001). In less developed countries, family structures tend to be more traditional.

CAUSES OF FAMILY-STRUCTURE CHANGES IN THE UNITED STATES

Discussions of the causes of these major family structure transformations can be grouped into two categories. The first category includes significant cultural transformations in the United States, where norms and values regarding marriage, divorce, sexuality, and so on have changed extensively. Opinion polls during the 1950s indicated that most Americans considered divorce, sex outside of marriage, and remaining single while in adulthood as somewhat deviant. These same behaviors are much more acceptable today, and the stigma associated with an adult not being in a traditional married-couple family has mostly disappeared (Giele 2003; Hackstaff 2003).

The second category of factors affecting the American family structure includes economic changes, such as the increased employment of women and economic-restructuring processes that result in fewer men with jobs that pay enough to support a family. Women have entered the job force in increasing numbers since the 1960s, making American women much more economically independent. The result is that divorce and remaining single have become more attractive alternatives, especially when compared to an unfavorable marriage (Giele 2003).

Additionally, beginning in the 1970s, an economic-restructuring process in the United States and other advanced societies has resulted in a significant decline in the number of manufacturing jobs and a corresponding increase in the number of jobs in the service sector (Morris and Western 1999; Sassen 1990). This economic-structure transformation has family-structure implications for two major reasons. First, a majority of the employees in the declining manufacturing sector are male, while female employees predominate in the expanding service sector. Consequently, there are increased employment opportunities for females and reduced employment opportunities for males. Second, most of the manufacturing jobs that have been lost were middle-income, while the new service jobs vary extensively in quality. While
some service jobs are high quality, many others are low-pay, low-skill, temporary, and seasonal (Albrecht 2004). In the past, even minimally skilled workers could often get a middle-income job in the manufacturing sector. This is no longer the case as workers who lack the skills to attain high-quality jobs are often forced to take low-quality jobs because many of the middle-income jobs no longer exist. The result is higher rates of unemployment and underemployment among males and shrinkage in the pool of male household heads financially able to support a family. Marriage thus becomes less attractive to women, the rate of unwed childbearing increases, and female-headed households proliferate (Albrecht et al. 2000; Wilson 1987, 1996).

CONSEQUENCES OF FAMILY-STRUCTURE CHANGES

In some sectors of society, the emergence of socially acceptable alternatives to the traditional family was met with euphoria because it was felt that the family had been an institution that generally suppressed women and limited individuality (Albrecht and Albrecht 2004). However, social science research is finding that many problems are emerging from changes in the American family (Haveman et al. 2001; Manning 2002; Waite and Gallagher 2000). A brief overview of the research on this topic indicates that men, women, and children in single-adult families all experience extensive disadvantages relative to their counterparts in married-couple families (Popeno 1996). Of the long list of disadvantages, only a few will be highlighted here. Single-adult families experience much higher levels of poverty, especially for females, with all of its attendant problems (Albrecht et al. 2000; Corcoran et al. 1992; McLanahan 1985). Children who grow up with only one biological parent have significantly lower educational achievements. These young people are much less likely to graduate from high school and to attend and complete college (Amato and Keith 1991; Downey 1995; McLanahan and Sandefur 1994; Raley et al. 2005; Zill 1996). Girls from one-parent families are much more likely to become pregnant as teenagers than girls from married-couple families, while boys are much more likely to become delinquent (McLanahan and Sandefur 1994; Wells and Rankin 1991). These differences remain even when economic conditions are considered. The advantages of being part of a married-couple family are apparent for adults as well as children. In a variety of ways, both men and women are healthier, happier, and more economically prosperous when married (Lichter and Graefe 2001; Nock 1998; Haveman et al. 2001).

FAMILY SUPPORT ACT OF 1988

SEE Fatherhood.

FAMILY VALUES

Family values refers to those norms that emerge from our experiences within the family structure and that inform our understanding of that social construction we call the family. Just as family structures have changed over time and vary across cultures, so too have attitudes about the family, its relationship to society, and its relative value in the social order. These changes within the family and society often have occasioned fierce debate and have led to contested claims about the nature and definition of fam-
Family Values

ily and those values that represent the many and varied forms of family life.

In the late-twentieth-century United States, political conservatives and liberals battled for culturally accepted definitions of the family and family values. According to sociologist James Davison Hunter, “the family is the most conspicuous field of conflict in the culture war” (1991, p. 176). This battle was an extension of a campaign by the Moral Majority, an organization formed in 1979 and composed of conservative, evangelical Christian activists. Among its stated tenets was opposition to feminism, gay rights, abortion, and pornography. The Moral Majority championed the patriarchal nuclear family as a biblical ideal and warned that the failure of the family would lead to the demise of American culture.

Family values as an ideological battleground came to prominence in U.S. political debate during the 1992 presidential campaign, when particular values were espoused by the “New Right,” a movement that brought together religious and political conservatives who emphasized individual responsibility and the primacy of Christian moral values coupled with traditional gender roles. One powerful New Right group, Focus on the Family, claims, for example, that the church, the family, and the government are the three basic institutions ordained by God for the benefit of humanity. The traditional family as described by such conservatives presumes heterosexual marriage, patriarchal authority within the family, and the production and care of children. The term “family values” was adopted by the New Right and functions in public debate as shorthand for this conservative ideology of family. “Family values” proponents often carve out their position over and against social forces which they believe threaten the traditional family; they are antichoice (in regards to abortion), antigay, against sex education other than promotion of strict abstinence, against hate-crime legislation, against the separation of church and state, and against a host of other issues that they believe threaten the traditional family structure.

History tells us that rather than privileging the nuclear family, definitions of the family have changed with time and culture, as have the values attributed to family. In classical Greek culture, for example, the pateri-familias (the male head of a household) was responsible not only for his immediate family but also for his current slaves, former slaves who were now clients, hired laborers, and sometimes business associates or tenants. And even in the ancient world there were disagreements about the value of the family: The philosopher Aristotle thought that family life was an obligation one fulfilled for the good of society, whereas Plato argued in The Republic that private, individual families detracted from the social good.

Historian Stephanie Coontz notes in The Social Origins of Private Life (1988) that the model of the nuclear family idealized in contemporary conservative politics emerged in the United States after the Revolutionary War as a response to changing economic and political realities. The Industrial Revolution provided new sources of income, facilitating the growth of a middle class. The wives of this emergent class were expected to devote themselves to the domestic sphere; their most important political contribution was to raise patriotic children while men worked outside the home to support the family and society. This was, of course, a privileged ideal that was not realized in, for example, slave families. Even today, poor and working-class families continue to find it difficult to thrive outside of extended kinship networks that provide both financial and emotional support. With an increasingly diverse U.S. population, traditional “family values” fail to account for the variety of family structures that emerge from different ethnic and cultural backgrounds.

Despite conservative claims that traditional “family values” are divinely ordained and hold the key to the ideal society, recent social science research indicates that values are of secondary importance when it comes to social mobility as an indicator of success. In a longitudinal study Patrick L. Mason assessed the importance of family values and class status on interracial inequality and intergenerational mobility (1999). Mason found that although family values do have some effect on economic mobility from one generation to the next, class considerations (and the intersection of these with race) are more significant in predicting inequality. Put another way, although values may shape our perception of our place in society, material considerations have a greater influence on our ability to actually change that place.

Any contemporary attempt to define “family values” must take into account the multiple and varying forms in which family life takes place in diverse communities, including single-parent families, unmarried heterosexual couples with or without children, gay men and lesbians with or without children, and other nontraditional groupings who form “families of choice.” The family is a cultural construction that has undergone multiple transformations throughout history without being destroyed. Despite “family values” rhetoric to the contrary, the family will survive future transformations, opening new horizons of human affiliation and identity.

BIBLIOGRAPHY

The practice of the subsistence compromise defines who are peasants. The practice of the subsistence compromise is clearly seen in most photographs of peasant cultivation practices that reach the media. These photographs show women planting rice sprouts in ponded fields, or dibbling maize or sorghum seeds into poorly prepared ground, or hoeing a patch of maize or sorghum overgrown with weeds, or harvesting grain with a child strapped on their backs.

Where are the men for this sustained labor? The only labor that is gender specific to men is plowing and digging potatoes, yams, and cassava. Almost all of the rest of the labor of cultivation is done by women and children. This is why high birthrates are desirable in peasant societies. Children can do much of the agricultural labor that is gender specific to women.

**PROXIMATE CAUSE**

In order to live by subsistence labor norms, peasants willingly endure seasonal hunger in poor crop years and risk famines in consecutive poor crop years. Before the mid-twentieth century, there were few roads or vehicle tracks into peasant villages. Starving peasants fled their villages in search of food (as Irish peasants did) or watched their children starve so that some adults would survive. During the second half of the twentieth century, roads or vehicle tracks were built into most peasant villages. When there was severe hunger, food donations arrived from central governments (to prevent mass migrations to cities that governments could not control) or food was donated by nongovernmental agencies. Donated food was essential to prevent starvation because peasants produced few commodities to sell for money to purchase food.

**ULTIMATE CAUSE**

The marginal food safety of peasant households in normal crop years is due to deficient labor applied to cultivation. The subsistence compromise produces no food surplus for consumption in consecutive poor crop years, and peasants experience privation. The cumulative effect of consecutive poor crop years is famine conditions.

**Subsistence Social Values** This is an unfamiliar concept for most people in commercial cultures. They find it difficult to believe that cultivators voluntarily produce subsistence amounts of food when increased labor expenditures, especially by males, could produce abundant harvests.

Peasants use four strategies to minimize agricultural labor and, at the same time, produce sufficient food in normal crop years to last until the next harvest. They practice cultivation techniques requiring minimal labor expenditures; they control land use with some variety of communal tenure so that a village’s arable land can be continually divided to accommodate additional households; they have many children to whom they can transfer labor at young ages; and they mitigate the worst effects of deficient harvests by sharing food among village households.

**Analysis** The welfare of peasant households does not depend on the acquisition of money. It depends on con-
Famine

trol of land use. When peasants control land use they can control labor expenditures and this means performing subsistence labor norms in cultivation. Peasant households can and do reject the earning of money incomes because earning money incomes requires continuous labor. As long as they control land use they have little interest in performing continuous wage labor (commercial labor norms). The reciprocal of subsistence labor norms is accepting privation in poor crop years.

Most economists do not recognize the distinction between subsistence labor norms (subsistence social values) and commercial labor norms (commercial social values). They assume that all persons want to earn money incomes and willingly perform commercial labor norms to acquire sufficient money to constitute an income. This is a false assumption. Economists make this assumption because they confuse monetization with commercial social values. Almost all peasant societies are monetized.

Peasants, however, want to acquire sufficient money to purchase a limited number of manufactured items. The most commonly purchased items are textiles, edged steel tools, steel cooking pots, plastic buckets, and sandals. After they have acquired enough money to purchase these items they cease laboring to produce additional products for market sale. Anthropologists call the money acquired to make these purchases a target sum.

Peasant households can subsist without the use of money as many do in the highlands of Papua, Indonesia, and Indian villages where the Hindu caste system operates. Households subsist without the use of money because the items they purchase can be made by resident artisans (pottery cooking pots, hand-loom textiles), as they were in the past. These items have a customary barter value, usually measured by handfuls or pots of grain.

It is, however, advantageous to purchase manufactured items because they have greater utility and durability. It is also advantageous to purchase them because the labor expended to produce products for market sale is less than that required to make artisan products, and much of this labor can be done by children. If households grow a small amount of food for sale, this is their exchange commodity. In poor crop years, however, it is eaten and no purchases are made of manufactured items. Households subsist without the use of money.

Most economists do not understand that money incomes do not exist in peasant villages. Economists, however, create them by assigning a money value to the harvest of peasants or to the number of hours of labor they assume were expended to grow a household’s annual food supply. In reality, the food grown by peasants has no money value. If it were sold, peasant households would starve. Likewise, the labor that is expended to grow a subsistence food supply has no market value because no money is received.

Economists create fictitious money incomes for peasant households in order to compare the welfare of peasant households with the welfare of households in commercial cultures. Fictitious incomes are created for peasant households by applying the techniques of financial analysis to subsistence cultures. Fictitious incomes created by economists make peasants poor in relation to the money incomes earned by households in commercial cultures. Peasant households, however, are not poor. They are subsistent. Sometimes economists use terms like subsistence income, nonwage income, implicit income, leisure income, or income concept to indicate that they know the incomes they have created are fictitious; however, they continue to compare real and fictitious incomes. The result is confusion.

The fictitious incomes created by economists cannot be used to compare the welfare of households in subsistence and commercial cultures because incomes in commercial cultures are real money. Real money incomes measure household welfare in commercial cultures because households require money to purchase their food, clothing, and housing needs. Financial analysis operates with reasonable efficiency in commercial cultures but has universally failed to measure household welfare when applied to subsistence cultures.

Creating fictitious incomes for peasant households creates huge distortions in policies recommended by economists to increase food production in peasant nations. The failure of economists to recognize the fundamental difference between subsistence and commercial labor norms has largely contributed to the continual failure of policies that economists recommend to initiate economic development. Economic development must begin with producing assured food surpluses in all crop years in order to feed full-time wage laborers living in cities. The failure of their policies is most obvious in sub-Saharan Africa and in many Latin American nations.

Increasing food production requires different policies from those recommended by economists. As the term political economy indicates, political policies precede economic policies. Unfortunately, most economists are poorly prepared to recommend political policies because their training is financial and they are indoctrinated to believe that money incomes are the universal way of measuring household welfare.

SUMMARY

The famines that occurred in the last twenty years of the twentieth century were due to war. Peacetime famines have been avoided by food gifts to households in affected peasant societies. Peacetime famine conditions will continue to recur in peasant societies until central govern-
ments enforce a change in land tenure from communal to freehold so that money taxes can be collected on agricultural land. In freehold tenure, households that practice the subsistence compromise and fail to pay money taxes can be evicted and forced to become supervised, paid agricultural laborers who can produce assured food surpluses.

FANON, FRANTZ
1925–1961

A psychiatrist, a revolutionary, and a leading theorist of the Algerian national liberation struggle, Frantz Fanon was born on June 20, 1925, on the island of Martinique. He studied medicine in France and specialized in psychiatry. In 1953 Fanon began working as a psychiatrist at the Blida Psychiatric Hospital in Algiers, Algeria, where he supported the Algerian struggle against French colonialism. Fanon’s dedication to this cause led to his expulsion from Algeria by the French authorities at the end of 1956. To continue his fight, Fanon moved to Tunis, Tunisia. In 1961 he fell ill with leukemia, and received treatment in the Soviet Union and later in Bethesda, Maryland, where he died on December 6, 1961.

Fanon played an instrumental role in the theorization of colonial desire, the dynamics of oppression, and the consequences of blackness. Among the sociohistorical and political issues that influenced his work and intellectual quest are the colonial history of Martinique, the manifestations of racism in France and in French colonial medicine, and the intricacies of the Algerian struggle. His work also shows, among other things, the influence of existentialist philosophy and the négritude movement. Fanon’s thought, in turn, inspired a number of liberation movements and civil rights struggles.

Fanon’s concerns are intimately linked to the history of Martinique, and more specifically to its experience of slavery and colonialism. Such concerns are reflected in his exploration of the power dynamics in the colonial world and the characteristics of two mutually constitutive “types”: the colonizer and the colonized. Not only does Fanon probe the nature of these two categories in The Wretched of the Earth (Les damnés de la terre, 1961), but he also examines the elements and associations that contribute to, and result from, the establishment of this binary. In his analysis of the effects of colonialism on both colonizers and colonized, Fanon presents this institution as a system of exploitative oppression based on forms of psychological conditioning leading to the production of resentment and to the propagation of violence. This violence originates in the colonial movement and results from the colonizers’ attempts to destroy “native social forms … and systems of reference of … [native] economy, the customs of dress and external life” (Fanon [1961] 1963, p. 40). This issue is important to note since many critics who claim that Fanon advocated the use of violence forget that violence is inherent to the colonizers’ strategies of oppression.

Throughout his analysis of the psychology of the Negro in Black Skin, White Masks (Peau noire, masques blancs, 1952), Fanon insists on the necessity of perceiving blackness as a “lived experience,” shaped not only by the gaze of whiteness but also by a state of alienation resulting from economic injustices and the “epidermalization” of the condition of inferiority (Fanon [1952] 1967, p. 11). In this book based on his observation of the condition of the Negro in the Antilles, Fanon also underlines the role that language plays in shaping the interactions within the black community on the one hand and between black people and their fellow white people on the other. Such a role is highlighted by Fanon’s affirmation that “to speak is to exist absolutely for the other” (Fanon [1952] 1967, p. 17). In this context, language reflects and shapes the self through the transmission of a specific worldview. Advocating the need of black people to achieve liberation from their psychoexistential complex, Black Skin, White Masks also probes how gender interacts with “color” to produce specific power-based structures informing the interaction between women of color and white men, as well as men of color and white women.

Among Fanon’s other significant contributions is the theorization of the role of the “native intellectual” in addressing the specific needs of struggles for justice in his or her country. Fanon also highlighted the role of the native intellectual in negotiating the problems pertaining to the conceptualization of national consciousness and resulting from the gap between the educated classes and the underprivileged masses. This negotiation is crucial in shaping ways of “acting back” and strategies of resistance described in The Wretched of the Earth.

Continuing his examination of the struggle against colonialism, Fanon analyzed the specific case of the Algerian liberation struggle, detailing its contexts and
components in *A Dying Colonialism* (**L’An V de la révolution algérienne**, 1959). This book, which explores the conflict between old values, transitional identifications, and the new Algerian nationalism, details the elements contributing to the formation of an alternative sense of national identity in Algerian society. *A Dying Colonialism* examines such issues through the discussion of the shifting symbolism of the Algerian women’s veil; the relationship between resistance to the radio and the Algerians’ desire to preserve social stability and traditional sociability; and the trauma resulting from changes in traditional family structure and the forced separation of family members. In this book, Fanon also shows how medical knowledge functions as a tool of power; more specifically, he argues that medicine can be seen, in certain situations, as an extension of the colonizer’s control over the colonized society.

An equal concern with unmasking the mechanisms and networks of power in its various forms and local as well as global dimensions permeates Fanon’s *Toward the African Revolution* (**Pour la révolution africaine**, 1964). This book is a collection of essays, notes, and articles, most of which were published in *El Moudjahid* (roughly translated as “the militant”), the underground newspaper of the Algerian National Liberation Front. A number of these writings probe the connection between French strategies in the Algerian War and the international scene in the United States and Europe. These works also examine the interdependence of individual liberation, anticolonial struggles, and the birth of national consciousness; the Algerian revolution and other liberation struggles in Africa and the Caribbean; and the end of colonialism and the resulting racism among the proletariat in the colonizing countries.

Throughout his life and career, Fanon probed the complexity of the colonial encounter and its aftermath. To account for its multilayered nature, he drew on a number of disciplines, including medicine, sociology, psychiatry, and literature, in a humanistic gesture reflecting his uncompromising dedication to the cause of the oppressed.

**FARSIGHTEDNESS**

Our religions, mythologies, and fables admonish us to overcome temptation, exercise self-discipline, and heed the future—consider Adam and Eve, Odysseus, and the Ant and the Grasshopper. Social scientists too offer helpful strategies for increasing willpower and avoiding indulgence (e.g., Ainslie 1975; Trope and Fishbach 2000; Werttenbroch 1998). The seemingly universal espousal of prudence and farsightedness as noble goals is reflected in the voluminous literature in the social sciences on self-control. This body of research is premised on the notion that people are shortsighted (myopic) and easily tempted by hedonic “sins,” such as overbuying (onioniomania), splurging on tasty but unhealthy food, and indulging in luxuries (see, e.g., Prelec and Herrnstein 1992; Thaler 1980).

An alternative research paradigm challenges the universality of myopia and proposes that people often suffer from a reverse self-control problem, namely excessive farsightedness (“hyperopia”) and overcontrol (Kivetz and...
Simonson 2002b; Kivetz and Keinan 2006; Keinan and Kivetz 2007). Such hyperopia leads people to deprive themselves of indulgence and instead overly focus on acting responsibly, delaying gratification, and doing “the right thing.” Research on farsightedness examines the underlying processes (e.g., guilt, justification), the way people cope with hyperopia (e.g., by precommitting to indulgence), and the consequences of overcontrol (e.g., long-term regret).

Ran Kivetz and Yuhuang Zheng (2006) shed light on the antecedents of hyperopia by highlighting the role of justification and guilt in self-control decisions (see also Kivetz and Simonson 2002a). Building on prior analyses in the social sciences, they propose two complementary routes to justifying self-gratification: the first through hard work or excellent performance (an entitlement justification) and the second through the attainment of indulgence without depleting income or monetary resources. Consistent with the two routes to justification, it is demonstrated that (1) higher required effort enhances preference for indulgence rewards over more prudent necessities, but a reverse effect is observed when the interchangeability of effort and income is implied; (2) providing (bogus) excellence feedback on an effort task enhances choices of indulgence, unless the interchangeability of effort and income is suggested; and (3) sensitivity to effort and excellence (i.e., justification) cues is greater for individuals who experience stronger (chronic or manipulated) guilt.

EVIDENCE AND REMEDIES OF HYPEROPIA

Kivetz and Itamar Simonson (2002b) provide a more direct examination of the notion of excessive farsightedness and the strategies that people use to overcome this (reverse) self-control problem. They found that a large segment of people perceive themselves as having insufficient indulgence and seek ways to correct this imbalance in their lives. Such people force themselves to indulge in an attempt to avoid default forms of spending on utilitarian necessities and/or savings. In particular people who have difficulty choosing items that are perceived as indulgences or luxuries (e.g., a cruise) over necessities (e.g., saving for college education) and cash in everyday decisions use precommitments to future hedonic experiences. For example, a substantial segment of people choose hedonic luxury awards over cash of equal or greater value (the choices and incentives are real). People explain such choices based on the need to precommit to indulgence, to make sure that the award does not end up in the pool of money used for necessities.

Kivetz (2007) provides additional direct evidence for the concept of hyperopia (excessive farsightedness). It is shown that people select pleasurable vices when the consequences of their decisions are psychologically distal (e.g., temporally delayed, hypothetical, improbable, abstract, or self-irrelevant) but reverse their decisions when the consequences are psychologically proximal (e.g., temporally imminent, real, vivid, or self-relevant). These reversals are more pronounced among people with a chronic tendency to experience guilt.

CONSEQUENCES OF HYPEROPIA

Kivetz and Anat Keinan (2006) investigate the consequences of hyperopia for people’s well-being and long-term feelings. The extant literature on self-control suggests that people not only yield to temptations they had originally planned to resist but also subsequently reverse their preferences and regret their myopic behaviors (e.g., Schelling 1992). Although yielding to temptation certainly can be harmful, Kivetz and Keinan argue that excessive farsightedness can also have negative long-term consequences. In particular they propose that with the passage of time, choices of virtue over vice (e.g., work over pleasure) increasingly evoke regret. Accordingly they demonstrate that increasing the temporal separation between the actual decision and its assessment enhances the regret (or anticipatory regret) of righteous choices. Building on research on self-control and on affect (e.g., Kivetz and Simonson 2002b; Kahneman 1995; Metcalfe and Mischel 1999), Kivetz and Keinan show that greater temporal perspective allows people to escape the influence of indulgence guilt and causes them to experience a wistful feeling of missing out on the pleasures of life.

A great deal of research in psychology, economics, marketing, and other social sciences has examined self-control and time inconsistency. Such research has relied on a myopic premise. Late-twentieth-century and early twenty-first-century research advances an alternative perspective, namely that of excessive farsightedness and over-control. By exploring what is essentially a reverse form of self-control, this research contributes to a fuller understanding of self-regulation as a dynamic and general process. Some key discoveries that are diametrically opposed to the myopic premise include:

- the finding that people require special entitlement justifications (hard work, excellence) to indulge;
- the finding that people are motivated to work harder for hedonic luxuries than cash equivalents but are willing to spend more money on the latter;
- the finding that people perceive themselves as suffering from excessive farsightedness and consequently correct this imbalance in their lives by precommitting to future hedonic experiences;
the finding that people are more likely to precommit to indulgence and to select vice when the consequences of their decisions are psychologically distal (e.g., temporally delayed, hypothetical, or abstract);

the detrimental impact of excessive farsightedness on well-being in the long run; that is, righteous choices of virtue over vice give rise to increasing regret over time, and considering long-term regret motivates people to select indulgence and luxury; and

the fact that the preceding findings are more pronounced among people who experience stronger (chronic or manipulated) indulgence guilt.

FASCISM

Fascism is a reactionary and revolutionary ideology that emerged across Europe after World War I. Fascism was partially developed in Italy and became fully developed in Germany as a reaction against the unrestrained liberal capitalism of the nineteenth and early twentieth centuries, which promoted individualism over communal organization. Fascism as an ideology is anti-Marxist in its militarization of culture, society, and the economy and its rejection of social reforms as a means to create community. As in communism, fascism emphasizes the primacy of the collective unit; however, fascists reject communism’s internationalism and instead define the community as a racial group whose passionate, heroic sacrifice for the nation will fulfill its historical destiny.

Fascism also promotes the adulation of a dictatorial figure to act as a strong representative of the Volk (the “people”) in this process. Fascists argue that true democracy exists only under these specific conditions, thereby creating a myth of volkish communal heroism that relies on militarism for its success. Since fascists think in terms of absolute enemies of the people, they view imperialistic war as an inevitability of the rise of fascism. The goals of war are twofold: first, to resolve “land hunger” by expanding the nation’s access to land, natural resources, and labor of native populations and, second, to solve domestic economic and political crisis (usually due to economic depression that causes high unemployment and challenges to the new one-party state). They therefore stress the virtues of a warlike culture: authoritarianism, unity of methods and goals, discipline, and an abhorrence of political dissent. The creation of an active, warlike citizenry is what distinguishes fascist regimes from authoritarian or dictatorial ones.

CHARACTERISTICS OF FASCIST SOCIETIES

Fascists solidified their power by stripping citizens of their individual rights and subordinating them to the will of the
collective. A single-party political system that used terror, a secret police, and a strong military established a dictatorship controlled by a new social elite representative of the party. The hierarchy differed from that of other social systems in that it was not defined in class terms, but rather in terms of service to the nation. Because of this distinction, fascist states introduced a new form of social mobility that appealed to many citizens. The fascist government also succeeded in co-opting the economic system into the national sphere. Capitalist economics continued in the preservation of private property, though high party officials ensured the alliance between industrial and agricultural sectors and the state. The exploitation of workers in the form of low wages and high production quotas created economic growth, thereby fulfilling the promises of fascist governments to solve the problems of high unemployment caused by economic depression. In these ways, fascists ensured the loyalty of worker, peasant, industrialist, and businessman.

The heavy use of propaganda was another hallmark of fascist politics through its creation of the myth of the volkish leader whose destiny was to resurrect the greatness of the Volk. Films, books, signs, leaflets, and artistic productions attempted to present fascism as a new form of spirituality by espousing the “eternal truths” of the state through the repetition of slogans and symbols. Organizations such as clubs and youth groups and public displays of nationalism (in the form of parades or rallies) attempted to destroy private and individual identities by exalting a communal one. Censorship stripped intellectuals of their creative freedom and demanded that they produce warrior-peasant art that reflected the racial superiority of the Volk. Additionally, state-sponsored architectural projects embraced themes of sacrifice and national greatness through the construction of its war monuments and government buildings. Because fascism proclaimed to be the mouthpiece of a lost moral system, psychological conversion of the masses was essential to its success.

HISTORICAL EXPLANATION FOR THE RISE OF FASCISM

The roots of fascism can be traced to the political climate of European society before the outbreak of World War I in 1914. At the turn of the twentieth century, the international tensions that would soon lead to war in Europe were already apparent. Most members of the rising bourgeoisie supported their European governments because they greatly benefited from successful nationalist industrial and colonial expansion in the late nineteenth century. The working classes, however, were not benefactors of industrial and colonial growth, and socialist politics were strong across Europe. The rise of minorities’ middle classes—Slavs in the Habsburg Empire and Jews every-

where in Europe—also threatened traditional ethnic majorities. Nationalists at this point rejected their liberal roots and became more conservative as nationalism developed into an ideology that protected the rights of the ethnic community over those of the individual. Rightist parties at the turn of the century appealed mostly to the traditional middle and upper classes, those that stood to lose the most through the rise of workers’ movements and new privileged ethnic groups. Persuading the working classes into rejecting the internationalist foundation of Marxist politics and accepting the nation as a protective body soon became the primary goal of rightist parties in the decades preceding the outbreak of World War I. This development led conservatives to define the nation in ethnic terms. The rise of nationalism as a condemnation of “others” allowed for the emergence of fascist politics across Europe in the 1920s and 1930s.

Fascism developed into mature political movements in European societies whose citizens experienced a recent, rapid, and intense possibility of social mobility as a result of concentrated industrial growth that threatened to destroy traditional hierarchy in the interwar period. Social anxiety over recent processes of modernity heightened when the United States stock market crashed in 1929 and the Great Depression paralyzed European economies. Fascism became a viable political response for millions of Europeans when their parliamentary systems failed to provide adequate economic relief in the 1930s. The success of fascist politics additionally depended upon the existence of a substantial volkish population, one whose identity could be interpreted as being representative of a greater national entity and used by fascist leaders as a symbol of past, organic national greatness. Therefore, the states that supported fascist politics on a national level in the 1920s and 1930s, mostly in Central and Eastern Europe, sustained substantial agricultural economies at that time. It is also notable that World War I left an unresolved national question, irredentist, colonial, or a high percentage of “outsiders” within national boundaries, in the countries that became fascist in the interwar period—Italy, Germany, Romania, Hungary, Austria, Croatia, and France. Fascist promises of a return to national greatness resonated with the masses who viewed their economic suffering as a social injustice. France is the exception to this pattern in that its fascist government—the Vichy regime—enjoyed very little popular support and was a puppet of the Nazis rather than a legitimate state. Fascism in all of its manifestations can be seen as one response to the social, economic, and political crisis that accompanied the process of modernity in Europe.

The emergence of Italian fascism deserves special attention because of Benito Mussolini’s role in fascist ideological development. Mussolini, fascist dictator of Italy from 1922 to 1943, first used the term fascism in 1919 to describe this new political ideology of individual subordi-
nation to the ethnic community as a method of attaining national greatness. Mussolini developed this belief in the strength of the community as an active and politically prominent socialist during his youth. Like many socialists, Mussolini was critical of the politics and economics of European liberal capitalism. In Italy's case, the last quarter of the nineteenth century and the first decades of the twentieth century were years of grave economic crisis, primarily due to its ineffectiveness in industrializing and the weakness and inefficiency of its governments. Italy's lack of natural resources perpetuated a largely agricultural economy that was unable to support imperialist expansion, causing international embarrassment in a time when national greatness on the continent was largely defined by the building of empires abroad.

After World War I, Mussolini came to believe that socialist internationalism would only serve to subordinate Italy to more powerful European neighbors who had failed to reward his country adequately for its Allied support during the war and turned to rightist politics. In 1919, Mussolini founded the Fascist Party and defined fascism as a technique for gaining and solidifying power through the use of violent action. Fascism demanded first and foremost the cultivation of military discipline and a fighting spirit in every Italian citizen. Unlike Marxist theory, which believes in an end to the process of history through a democratically based revolution that establishes a communist state, Mussolini's fascism defined history as constant struggle through constant war. The necessity of action required the adulation of a leader who would manage his country's destiny through acts of war and violence. Complete confidence in the decisions of the leader, Il Duce, as Mussolini referred to himself, needed to be blindly obeyed in order for national goals to be met. Mussolini pointed to Italy's weakened economic state after the war as proof that such a leader was necessary for Italian recovery.

In 1922, Mussolini's fascist militia marched on Rome and he became the prime minister of Italy. Between 1922 and 1927, Mussolini concentrated on fascist state-building. The state and the Fascist Party became a single entity that oversaw the alignment of the legislative, executive, and judicial bodies with nationalist goals. Mussolini asked Italians to sacrifice their individual identities in order to establish Italy as the new leader of mankind. He further legitimized his dictatorship by pointing to the rise of fascist parties across Europe as evidence that parliamentarianism and liberal democracy were decadent political and social values and that fascism was indeed the new path of modernity.

What differentiated Italian fascism at this early stage from other young fascist movements across Europe was its rejection of anti-Semitic sentiment. This distinction is mostly due to the lack of a discernable Jewish population in Italy. Instead, Italian exposure to African populations during failed colonial ventures made Africans the targets of Italian racist nationalism during the interwar period. Mussolini integrated this race doctrine into the construction of his dictatorship but never fully developed it. Rather repulsed by the racist program of the National Socialists (Nazis) in Germany, Mussolini instead directed his energies toward imperialist expansion rather than cultivating an ethnically pure Italian state.

Anti-Semitism was the distinguishing feature of mature fascism developed by Adolf Hitler in Germany. Hitler's fusion of race doctrine—the belief in the natural inequality of human races and the superiority of the Teutonic race—with Mussolini's philosophy of power created a particularly virulent and highly destructive form of fascism. The anti-Semitic flavor of Imperial German society laid the foundations for the rise of racist nationalist politics in the interwar period. The increase of Jewish presence in trade, finance, politics, and journalism, particularly in Berlin, around the turn of the twentieth century fueled conspiracy theories about a Jewish “infiltration” of German society. Hitler's fascist National Socialist Party, begun in 1919 as the German Workers' Party, was an anti-Semitic, supra-nationalist political organization whose proclaimed goal was to protect the ethnic German community at all costs. The Nazis succeeded in earning millions of German votes in the late 1920s and early 1930s with its strong repudiation of the Versailles Treaty coupled with messages of moral and economic rebirth through the destruction of “Jewish” market competition, the annihilation of European Jewry, and territorial expansion. Hitler and the Nazi Party attempted to fulfill the promises of his propaganda through the creation of a totalitarian state in Germany. From 1933 to 1945, the Nazis exercised total control over the German population and conquered much of the European continent. The fascist period of German history was additionally responsible for the deaths of approximately six million Jews and three million Slavs, Roma, homosexuals, political dissidents, and other “undesirables” during the Holocaust.

INTERPRETATIONS OF FASCISM
It has been difficult for historians, political scientists, psychologists, and sociologists of fascism to agree on a single explanation for the rise of fascism in some countries but not in others. One leading interpretation supports the notion that fascism was an experience unique to certain countries, pointing to some kind of predestination of radical conservative nationalism. The second prominent interpretation is that fascism was a reaction to the failure of European liberalism to make good on its promises of promoting every individual's right to social mobility. This
interpretation puts the rise of fascism in an international context of the struggles of European modernity.

FATHERHOOD

Issues of fatherhood have received considerable attention since the 1990s in academic, practice, and policy discussions as well as in the public domain. This focus on fatherhood, which subsequently came to address responsible fathering, reflects an assumption: that the meaning and enactment of responsible parenting are at the heart of social and cultural debates about the individual and combined roles of families and society in ensuring the health and well-being of children. Throughout the 1970s and 1980s most of the cultural debate about mothers highlighted the question: What, if anything, should mothers do outside the family? By the end of 1990s the debate about fathers had refocused the question to: What should fathers do inside the family (see Doherty, Kouneski, and Erickson 1998)? Several related questions were posed: What role should fathers play in the everyday lives of their children, that is, beyond the traditional breadwinner role? How much should they emulate the traditional nurturing activities of mothers, and how much should they represent a masculine sex-role model to their children? Advocacy organizations and those in the public domain asked: Is fatherhood in a unique crisis? The discussion that follows provides an overview of the background and context of these questions, the resulting effort, and the current status of discussions in the field.

BACKGROUND AND CONTEXT OF THE ISSUES

Prior to the 1960s research and policy on family development were dominated by intact or nuclear family models. The role of fathers was framed within a decidedly Euro-American interpretation of family functioning in which fathers provided for the economic well-being of their children and mothers ensured their children’s developmental progress (see Coltrane and Parke 1998; Gottman and Katz 1989; Parke 1996; Pruett and Pruett 1998). Much of family research through the 1970s also focused on the degree to which ethnically diverse families, particularly African American families, adhered to this model (see Coleman et al. 1966; Katz 1993; McDaniel 1994; Moynihan 1965, 1987). Not until the resurgence of interest in family studies in the 1990s did research or policy highlight the diversity of family functioning, interactions, and expectations embedded in the cultural and ethnic histories of families and communities in the United States (see Anderson 1990, 1999; McDaniel 1994; Zuberi 1998).

Much of the visibility of fatherhood can be traced to the passage of the 1988 Family Support Act, which called attention to the failure of many nonresidential, noncustodial parents, mostly fathers, to contribute to the financial support of their children. However, the act did not distinguish among different types of fathers and appeared to assume that all fathers shared a common experience in terms of their marital status at the birth of their children, employment and employability, ability to contribute financially, reasons for absence, and the quality of their relationship with their children, families, and communities. Divorced, middle-class, educated, nonresidential fathers were grouped alongside low-income, unemployed, poorly educated fathers. Issues of class, race, and cultural practices were relatively unexamined except in noting the disproportionate numbers of single, African American, low-income mothers raising their children as well as low-income fathers who neither had custody of their children (noncustodial) nor resided with them (nonresidential).

Despite its limitations, the act was effective in generating interest about nonresidential fathers and acknowledging the growing numbers of fathers who lived apart from their children. It also prompted researchers and practitioners to raise critical issues about the failure of policies in general to address the diversity of fathers and the disparities in their circumstances. The complexity of a changing society was evident in the struggles being experienced by large numbers of children and families.
However, it was clear that to understand the causes and effects of father absence, the field also needed to address the causes and effects of father presence, expanding the apparent urgency to examine all types of fathers, irrespective of their coresidence with their children and families, social class, race, and family ties. The discussions that ensued positioned, as a priority, the common problems of father absence; its effects on children, families, communities, and society; and the downward spiraling of two-parent families, father presence, and marriage. They pointed to the need to uncover and understand how men enact their roles as fathers, (re)negotiate gendered and social expectations, and (re)engage with their children and families over the short and long term.

**RESPONSIBLE FATHERING**

Since the mid-1990s researchers have distinguished various types of father involvement; however, the resulting literature defines and describes father-child presence with increased, though still inexact, precision. The use of the concept responsible fathering reflects a relatively recent shift among academics and professionals away from value-free language toward a more explicit value-advocacy approach (see Doherty et al. 1998; Gadsden 2002; Gadsden and Hall, 1996). Responsible suggests an ought, a set of desired norms for evaluating fathers’ behavior. The term also conveys a moral meaning (right and wrong), since it suggests that some fathering could be judged irresponsible or nonresponsible. Michael Lamb and his colleagues (1985) offered the most influential scheme to organize the concept: (1) responsibility, the role that fathers take in ascertaining that their children are cared for and arranging for the availability of resources; (2) availability, fathers’ potential for interaction by virtue of being present or being accessible to their children (whether or not direct interaction is occurring); and (3) engagement, fathers’ direct interaction or contact with their children through caregiving and shared activities.

Several categorizing frameworks and measurement tools have been created since the mid-1990s, among them Vivian Gadsden and colleagues’ (1999) Fathering Indicators Framework (National Center on Fathers and Families), Rob Palkovitz’s (1997) list of 119 ways to be involved in parenting, Alan Hawkins and colleagues’ (2002) Inventory of Father Involvement, and the Lewin Group’s Evaluability Assessment of Responsible Fatherhood Programs (1997).

**THE CURRENT STATUS**

The study of fatherhood has progressed significantly as a field from the early 1990s to the early twenty-first century. In 1994 the National Center on Fathers and Families (NCOFF) was established at the University of Pennsylvania to create and implement a research agenda that took seriously the issues of practice, including a research database, the Fatherlit Research Database. The center and the resulting activities in the field demonstrated a consistent shift. For example, in fields such as developmental psychology, once characterized by a singular focus on mother–child relationships, the significance of the father in the daily routines of child support and nurturance was increasingly discussed. The implication of this work was that the role of fathers, and the family itself, was seen as contributing to the affection development of children; to the shaping of personality; and eventually to a sense of belonging, meaning, and socioemotional stability.

One might well ask, What has really changed in the field since the 1990s? Any review of data from the field reveals the measured but significant increase in focus and reach to multiple audiences. Through tracking of the FatherLit Database, NCOFF has systematically collected data on the number of refereed research articles and other research publications on fathers, including the creation of a journal, *Fathering*, in 2003. Although much of the discussion still dichotomizes the issues into father presence and absence and their effects, it also addresses specific questions such as fathers’ relationships with their children, the effect of father presence on young children, the role of fathers in homes, and the effects of father engagement on mothers.

Outside the United States the focus on fatherhood has been equally compelling. However, a persistent problem centers on the degree to which and the way research, practice, and policy are constructed and implemented across cultural and national borders. As is true in the United States, questions about where and how to situate fatherhood and fathering are a critical focus of discussion. For example, should fathering be aligned with child well-being? Is it more appropriately studied as an issue of family development and family functioning? How should it be examined within economic and legal considerations? What is the role of fathers in children’s lives?

In various parts of Africa (most notably South Africa) an increasing body of research and new programs have been initiated. Support for these efforts often began as grassroots initiatives but subsequently have been examined in relationship to family life, economic stressors, and the meaning of father presence and engagement. In *Baba: Men and Fatherhood in South Africa* (2006), edited by Linda Richter and Robert Morrell, chapters take up several of the concerns, questions, and problems that have been examined in the United States but with particular currency for explicating and understanding the cultural contexts in South Africa, such as migrancy, the experience of gold mine workers, Zulu-speaking men and father-
hood, and HIV/AIDS, to name a few (see also Madhaven et al. 2006 for a discussion of father presence in rural South Africa).

A. Bame Namenang (2000), in addressing related issues in Cameroon, similarly calls attention to the construction of father images, cultural practices, kin networks, and the ways fatherhood is situated within these larger familial and community contexts. Efforts throughout Europe, Australia, and the Caribbean reinforce the need to examine critically the cross-cultural and cross-national domains of fatherhood. Among the most well-known research is that of Margaret O’Brien (2004) in England, in which she takes up research and policy questions and the difficult intersections between programs and policies. Drawing upon work from large datasets in the United States, Alison Smith (2007) has used the European Community Household Panel to identify several trends throughout European countries, for example, cross-national differences in fathers’ participation in child care, in employment and pay for fathers versus nonfathers, and in the amount of time spent working (see also Jaipaul Roopnarine and Janet Brown’s [1997] work on Caribbean families).

At the same time programmatic efforts have increased and become better organized. A range of programs has emerged—from small, grassroots efforts to educational efforts to work affiliated with federally funded organizations. The National Practitioners Network for Fathers and Families; the National Fatherhood Initiative, which houses a federally funded clearinghouse; and the National Center on Fathering represent a few of these efforts, as does a group of experts representing different focuses—research, practice, and advocacy—and the National Fatherhood Leaders Group. Similar work is taking place throughout parts of Africa, Europe, Australia, and the Caribbean, much of it building upon practitioner efforts and cross-collaborations between the United States and groups abroad and supported by a range of foundations and governmental initiatives, including regional meetings in England, Jamaica, South Africa, and Australia. One example from England is Father Direct, the national information center that publishes guides and provides training, conferences, and briefings on fatherhood.

The interest in responsible fatherhood has both heightened and precipitated change. Work on fathers invariably points to the deleterious effects of father absence for children, families, communities, and society, including a focus on “fragile families” (see publications of the Center on Child Wellbeing at Princeton University; Garfinkel and McLanahan 2003; McLanahan 2006; McLanahan and Carlson 2004) and families experiencing hardship absent the supports necessary for optimal healthy development, with children thought to be especially at risk for poor academic achievement, juvenile delinquency and incarceration, victimization by violence and exploitation, and unmarried adolescent parenting (see also Shannon et al. 2002; Cabrera and Garcia-Coll 2004).

Finally, policy efforts have grown at all levels of government, though the question of “what constitutes a good father” persists (see Rosenberg and Wilcox 2006), as do issues related to father absence. For example, in a request for proposals from the U.S. Department of Health and Human Services (2006), the writers noted that in approximately 84 percent of cases where a parent is absent, that parent is the father and that if the trends continue, half of all children born in the early twenty-first century will live apart from one of their parents, usually their father, at some point before they turn eighteen. They also indicate that where families (whether intact or with a parent absent) are living in poverty, a significant factor is the father’s lack of job skills. An estimated 19,400,000 children (27 percent) live apart from their biological fathers. Of children under age eighteen not living with their biological fathers, 40 percent had not seen their fathers even once in the last twelve months.

**CLOSING THOUGHTS**

It is no surprise that the field of fatherhood and the larger field of family studies grapple with an array of difficult questions and uncharted terrain. What is needed in this still growing field are deepened analyses that reflect the ways fathers, children, and families shape and revise their identities within families and respond to the social and cultural expectations of home and society. Several issues are still relatively unexamined, among them the diversity of fathers, both middle-income and low-income men and families; families of color and immigrant families; the cultural and social factors that influence fathering practices and community expectations; children of incarcerated fathers; the engagement of fathers and mothers as parents and in relationship to their children; the effects of racial stratification on fathers’ engagement; preparation (through schooling and work) to assume the financial and emotional roles of fathering; issues of men’s health; and social vulnerability. In order for change to occur, a conceptual framework is critical—one that reflects a deep understanding of the multifaceted issues and possibilities to effect change in all communities where there are fathers and children.

BIBLIOGRAPHY

Vivian L. Gadsden
Joseph Feagin is a scholar, social justice advocate, professor, and leader in the field of urban sociology. Throughout his career, he has fought against the oppression of people of color within the United States. His passion for equity has essentially held a mirror to the country, reflecting the raw imagery of how the United States has historically oppressed people of color through social, economic, mental, and physical means. This reflection has at times caused those who view the issues of race conservatively to see Feagin’s work as unbearable. For example, in his book *The Professors: The 101 Most Dangerous Academics in America* (2006), the conservative author David Horowitz included Feagin on his list of “threats.” Horowitz claims that professors like Feagin “push” their liberal agenda onto college students, while at the same time stifling alternative viewpoints within the classroom. Regardless, many admirers of his work and efforts feel that he has spent a rich academic career attempting to answer the endless riddles of racial problems within the United States.

Joe Feagin was born in San Angelo, Texas, and he grew up in Houston during the Great Depression. After high school, he earned a degree in history, philosophy, and social ethics at Baylor University in 1960. He received a PhD in social ethics from Harvard University in 1966. He began his academic career as an assistant professor at the University of California at Riverside from 1966 to 1970. He went on to hold the positions of associate professor and full professor of sociology at the University of Texas, Austin (1970–1974 and 1974–1990, respectively). He has also been a scholar-in-residence at the U.S. Commission on Civil Rights (1974–1975) and a graduate professor at the University of Florida (1990–2004). In 2004 he was appointed the Ella C. McFadden Professor of Liberal Arts at Texas A&M University. Feagin has received countless honors and awards, including the Gustavus Myers Center Outstanding Human Rights Book Award in 1995 and 1996 and the Center for Healing of Racism Ally Award in 2006. He has twice been nominated for the Pulitzer Prize, and he served as the president of the American Sociological Association in 2000.

In his advocacy for social justice through the use of empirical and historical research and data, Feagin has explored the hatred that the white majority has toward people of color, especially blacks. He believes that this hatred is not only at the center of the foundation of the country, but that it is also the rationale for the current treatment of people of color. He has successfully correlated various problems that exist among people of color to the white racial frame that was first used successfully to disempower blacks through the means of social control. In fact, this white racial frame uses a manipulation of stereo-types of blacks and other people of color to galvanize the need for control over this population, who have historically been viewed as sexual and physical threats by white elites.

Feagin’s prolific scholarship has spanned over forty-two years and yielded thought-provoking contributions in over 40 published books, 180 journal articles and monographs, and numerous consultations on issues of racism, discrimination, police brutality, gender racism, and other such experiences of people of color. Since 1989, with the help of other colleagues, he has completed field research studies involving approximately 600 black Americans in regard to social problems. In addition, in order to bring forth the voices of the marginalized within his work, he has been involved within dozens of field research studies that use diaries, focus groups, and in-depth interviews. But because the sample respondents used in various segments of his work are not selected from a sampling frame, the “snowball” sampling technique he and other qualitative researchers use cannot always ensure unbiased estimates. Thus, this technique has been called into question by some, particularly by pure quantitative researchers.

Many researchers in the field, however, have adapted the technique because of its value in researching groups that are traditionally difficult for researchers to gain access to. Overall, Feagin has helped give a voice to the voiceless and marginalized populations within the United States.

FEDERAL RESERVE SYSTEM, U.S.

Of all the central banks in the world, the Federal Reserve System ("the Fed") has one of the most unusual structures. The historic hostility of the American public to banks and centralized authority (which resulted in the demise in 1811 and 1832 of the first two experiments with central banking, the First and Second Bank of the United States) led the U.S. Congress to write an elaborate system of checks and balances into the Federal Reserve Act of 1913, which created the Federal Reserve System with its twelve regional Federal Reserve banks.

The writers of the Federal Reserve Act wanted to diffuse power along regional lines, between the private sector and the government, and among bankers, business people, and the public. This initial diffusion of power has resulted in the evolution of the Federal Reserve System to include the following entities: the Federal Reserve banks, the Board of Governors of the Federal Reserve System, the Federal Open Market Committee (FOMC), and around 2,800 member commercial banks.

FEDERAL RESERVE BANKS

Each of the twelve Federal Reserve districts has one main Federal Reserve bank, which may have branches in other cities in the district. The three largest Federal Reserve banks in terms of assets are those of New York, Chicago, and San Francisco—combined they hold more than 50 percent of the assets (discount loans, securities, and other holdings) of the Federal Reserve System. The New York bank, with around one-quarter of the assets, is the most important of the Federal Reserve banks because it conducts foreign-exchange interventions on behalf of the Federal Reserve System and the U.S. Treasury and also purchases and sells securities for the Federal Reserve System.

Each of the Federal Reserve banks is a quasi-public (part private, part government) institution owned by the private commercial banks in the district that are members of the Federal Reserve System. These member banks have purchased stock in their district Federal Reserve bank (a requirement of membership), and the dividends paid by that stock are limited by law to 6 percent annually. The member banks elect six directors for each district bank; three more are appointed by the Board of Governors. Together, these nine directors appoint the president of the bank (subject to the approval of the Board of Governors).

The directors of a district bank are classified into three categories: A, B, and C. The three A directors (elected by the member banks) are professional bankers, and the three B directors (also elected by the member banks) are prominent leaders from industry, labor, agriculture, or the consumer sector. The three C directors, who are appointed by the Board of Governors to represent the public interest, are not allowed to be officers, employees, or stockholders of banks. This design for choosing directors was intended by the framers of the Federal Reserve Act to ensure that the directors of each Federal Reserve bank would reflect all constituencies of the American public.

The twelve Federal Reserve banks perform the following functions:

- Clear checks;
- Issue new currency;
- Withdraw damaged currency from circulation;
- Administer and make discount loans to banks in their districts;
- Evaluate proposed mergers and applications for banks to expand their activities;
- Act as liaisons between the business community and the Federal Reserve System;
- Examine bank holding companies and state-chartered member banks;
- Collect data on local business conditions; and
- Use their staffs of professional economists to research topics related to the conduct of monetary policy.

The twelve Federal Reserve banks are involved in monetary policy in several ways. Their directors "establish" the discount rate (although the discount rate in each district is reviewed and determined by the Board of Governors) and decide which banks, member and non-member alike, can obtain discount loans from the Federal Reserve bank. Their directors select one commercial banker from each bank's district to serve on the Federal Advisory Council, which consults with the Board of Governors and provides information that helps in the conduct of monetary policy. Five of the twelve bank presidents each have a vote in the Federal Open Market...
Committee, which directs open market operations (the purchase and sale of government securities that affect both interest rates and the amount of reserves in the banking system). The president of the New York Fed always has a vote in the FOMC, another reason why it is the most important of the banks; the other four votes allocated to the district banks rotate annually among the remaining eleven presidents.

BOARD OF GOVERNORS OF THE FEDERAL RESERVE SYSTEM
At the head of the Federal Reserve System is the seven-member Board of Governors, headquartered in Washington, D.C. Each governor is appointed by the president of the United States and confirmed by the Senate. To limit the president’s control over the Fed and insulate the Fed from other political pressures, the governors can serve one full nonrenewable fourteen-year term plus part of another term, with one governor’s term expiring every other January. The governors (many are professional economists) must come from different Federal Reserve districts to prevent the interests of one region of the country from being over-represented. The chairman of the Board of Governors is chosen from among the seven governors and serves a four-year, renewable term. It is expected that once a new chairman is chosen, the old chairman resigns from the Board of Governors, even if there are many years left to his or her term as a governor. The chairman exercises enormous power because he is the spokesperson for the Fed and negotiates with Congress and the president of the United States. He also exercises control by setting the agenda of Board of Governors and FOMC meetings and by supervising the board’s staff of professional economists and advisors.

The Board of Governors is actively involved in decisions concerning the conduct of monetary policy. All seven governors are members of the FOMC and vote on the conduct of open-market operations. Because there are only twelve voting members on this committee (seven governors and five presidents of the district banks), the board has the majority of the votes. The board also sets reserve requirements (within limits imposed by legislation) and effectively controls the discount rate by the “review and determination” process, whereby it approves or disapproves the discount rate “established” by the Federal Reserve banks. The chairman of the board advises the president of the United States on economic policy, testifies in Congress, and speaks for the Federal Reserve System to the media. The chairman and other governors may also represent the United States in negotiations with foreign governments on economic matters. The board has a staff of professional economists (larger than those of individual Federal Reserve banks) which provides economic analysis that the board uses in making its decisions.

Through legislation, the Board of Governors often has been given duties not directly related to the conduct of monetary policy. In the past, for example, the board set the maximum interest rates payable on certain types of deposits under Regulation Q. (After 1986, ceilings on time deposits were eliminated, but there is still a restriction on paying any interest on business demand deposits.) Under the Credit Control Act of 1969 (which expired in 1982) the board had the ability to regulate and control credit once the president of the United States approved. The Board of Governors also sets margin requirements—the fraction of the purchase price of securities that has to be paid for with cash rather than borrowed funds. It also sets the salary of the president and all officers of each Federal Reserve bank and reviews each bank’s budget. Finally, the board has substantial bank regulatory functions: It approves bank mergers and applications for new activities, specifies the permissible activities of bank holding companies, and supervises the activities of foreign banks in the United States.

FEDERAL OPEN MARKET COMMITTEE (FOMC)
The FOMC usually meets eight times a year (about every six weeks) and makes decisions regarding the conduct of monetary policy, especially by setting the target for the policy interest rate and the federal funds rate (an overnight rate for loans between banking institutions). In addition, it also makes the decisions about reserve requirements and the discount rate (which play less of a prominent role in the conduct of monetary policy). The FOMC does not actually carry out securities purchases or sales. Instead, it issues directives to the trading desk at the Federal Reserve Bank of New York, where the manager for domestic open-market operations supervises a roomful of people who execute the purchases and sales of the government or agency securities. The manager communicates daily with the FOMC members and their staffs concerning the activities of the trading desk.

Frederic S. Mishkin
FEDERAL RESERVE SYSTEM, U.S.: ANALYSIS

A political compromise enabled Congress to find a majority to support the Federal Reserve Act of 1913. New York bankers wanted control vested in bankers, and favored a model based on the Bank of England. Rural and agricultural interests wanted political control to remain with the government. The compromise created twelve semi-autonomous Reserve banks controlled by bankers, with a Reserve Board in Washington, D.C., appointed by the president with the consent of Congress. The compromise left open the question of degree of independence: Who would make the decisions, Reserve banks or the Board?

Policy decisions were in fact limited. The authors accepted the international gold standard as a monetary rule and the real bills doctrine as an operating procedure. That limited scope for discretion in decisions about the timing of discount rate changes.

Almost immediately, conflict over decisions began between the Board and the Reserve banks. The banks, led by Benjamin Strong of the New York Reserve bank, dominated decisions until Strong's death in 1928. Strong and his associates soon recognized that the real bills doctrine had a major flaw: It implied that a central bank could control the quantities of money and credit by controlling their quality. Specifically, they concluded that efforts to prevent speculative lending would not succeed. The Board adhered to the real bills doctrine and, until 1933, the gold standard. The result of this policy was to deepen the Great Depression. The Federal Reserve was inactive from 1933 to 1951, under the control of the Treasury. In 1935 Congress approved changes in the Federal Reserve Act that shifted control of decisions from the Reserve banks to the Board of Governors. Once the Federal Reserve resumed active policymaking in 1951, the Board began to change procedures to strengthen its control. At the time, it lacked a clear vision of its proper objectives and how to achieve them.

Congress passed two pieces of legislation at the end of World War II (1939–1945). The Employment Act (1946) made a vague commitment to economic stability. The Bretton Woods Agreement (1944) called for fixed but adjustable exchange rates. Monetary policy could achieve domestic stability or exchange rate stability, but not both. The Federal Reserve and many others interpreted the Employment Act as a commitment to "full employment," and although the Reserve never defined what that meant in practice, it gradually came to mean unemployment rates of about 4 to 5 percent. Federal Reserve Chairman William McChesney Martin Jr. stressed the importance of maintaining low inflation and a fixed exchange rate, but he did not develop procedures to achieve either.

One reason for this failure was the effort to coordinate monetary and fiscal policy actions. A popular belief at the time held that coordination would contribute to stability and prosperity; overlooked was the loss of Federal Reserve independence and the increased political influence on monetary policy actions. The administration of Lyndon Johnson wanted the Federal Reserve to coordinate by keeping interest rates from rising so they could finance their persistent budget deficits at lower cost. The Federal Reserve did just that. Also, when it became concerned enough to act against inflation by reducing money growth in 1966, homebuilding declined sharply. Political pressures increased.

Mistaken beliefs about the conduct of monetary policy added to the problem. Economists developed the Phillips curve, relating inflation and unemployment, and policy makers used this construct to reduce unemployment rates by increasing inflation. They discovered after the fact that the reduction in the unemployment rate did not persist, but inflation persisted. The Federal Reserve tried several times—in 1969, 1973, and 1976—to reduce inflation. When the unemployment rose to 7 percent or more, they abandoned the efforts.

Persistent and rising inflation brought an end to the Bretton Woods System of fixed exchange rates. European nations and Japan became willing to give up the fixed exchange rate system in order to free themselves from the effect of U.S. inflationary policies. By the end of the 1970s it was apparent to all that instead of trading off lower unemployment for higher inflation, U.S. policy resulted in higher inflation and higher unemployment. Public attitudes changed, and the change affected some congressional leaders. President Jimmy Carter appointed Paul Volcker as chairman of the Board of Governors of the Federal Reserve. Volcker made two lasting changes. First, he reestablished Federal Reserve independence of political control. This was a necessary step, but it required an acceptance of responsibility for policy outcomes that Chairmen Martin and Burns had been unwilling to make. Second, he accepted the temporary increase in unemployment needed to convince the public that he would not return to inflationary policy. High real interest rates and falling real balances produced a severe recession, with the unemployment rate reaching 10 percent.

But Volcker succeeded. The Federal Reserve and many others adopted and repeated a new mantra, very different from the Phillips curve, that low inflation was the best way to assure low unemployment. From the 1980s to 2005 the United States experienced the two longest peacetime expansions in its history, with inflation generally modest. Despite large budget deficits in the 1980s and after 2001, variability of output and inflation declined to low levels. The public remained confident that monetary...
policy would remain sufficiently independent to prevent a return to the instability of the 1970s, and that helped to build a political consensus and popular support for low inflation.

**FEDERALISM**

Federalism is one of the most fundamental principles of the American political system. Federalism can be defined as a principle of government in which political authority is divided between a national government and a collection of state (or regional) governments, acting side by side and sharing a large geographical space. The authority of the national government is exercised supremely over many areas of public policy. For example, the national government carries out the military and diplomatic functions of the country, as well as other important issues of national concern. The state or regional governments are semiautonomous and distinct entities that provide a convenient structure through which officials can administer policies of immediate and direct relevance to citizens. Some of the key services provided at the state level that most directly affect citizens are police and fire protection, criminal justice, and primary and secondary school education.

In a federal system, national and state governments are entities that operate as two mutually exclusive spheres of authority, although their functions often overlap and this can be a source of tension. One commentator on the structure of intergovernmental relations in the American system of government, James Bryce (1838–1922), noted that “the system is like a great factory wherein two sets of machinery are at work, their revolving wheels apparently intermixed, their bands crossing one another, yet each set doing its own work without touching or hampering the other” (Bryce 1916, vol. 1, p. 318). Under a system of federalism, both the federal and state governments have their own constitutions from which they derive the authority to act on behalf, and for the benefit, of the people.

In the United States, the national Constitution is the supreme law of the land. This implies, in part, that the state government must recognize and respect the national Constitution, and that state governments must set up their state constitutions and enact their own laws in such a way that they avoid conflict with the national Constitution. Where such conflict emerges, it is generally understood that the state constitution must give way to the national Constitution. Because the national Constitution as interpreted by the Supreme Court supersedes state or regional constitutions in power and authority, state governments usually operate with less independence than they might like and with less independence than states in a confederacy or a league of nations.

Writing about the meaning of federalism, noted British authority K. C. Wheare (1907–1979) defined federalism as a “method of dividing powers so that the general and regional governments are each, within a sphere, coordinate and independent.” He further noted “that each government should be limited to its own sphere and, within that sphere, should be independent of the other” (McClelland 2000, p. 297). Because federalism requires that the national and state governments should each “be limited to its own sphere,” it becomes important for there to be a written constitution, which would define the boundaries of authority for each government. A written constitution is therefore one of the key characteristics of federalism. Without such a constitution, the national government can easily encroach upon or usurp the authority of the state governments, possibly leading to chaos.

**FEDERALISM AS A HAPPY COMPROMISE**

Federalism as practiced in the United States is what people around the world usually refer to when the word federalism is uttered or heard. It is based on one of the oldest written constitutions, the U.S. Constitution, which was ratified in 1787 after much eloquent and contentious debate over its content. The framers of the U.S. Constitution worked hard to establish a system of government they and their posterity could be proud of, a government that would “best secure the permanent liberty and happiness of their country” (Madison 1835, quoted in McClelland 2000, p. 293). The framers were not interested in setting up a central government, where political power would be concentrated in the hands of a national government, as was the case in prominent countries at that time, such as France and England. The framers were also not interested in continuing a confederate system because the Articles of Confederacy (the original governing charter of the United States) prevented the establishment of a strong and respected nation since the Articles created a natural inclination within the provinces to satisfy their own territorial interests rather than to secure the interest of the entire nation. The framers were, however, very much interested in a system that would reflect the wishes and preferences of
Federalism

the citizens, a system that would provide a high degree of independence and autonomy to the states while enhancing the international stature of the nation. Thus federalism as a theory of government was indeed an afterthought in that it emerged after the framers wrote and ratified the Constitution (McClelland 2000, p. 298).

Federalism is the product of a happy compromise in the formation of the nation and in its capacity to present a unified front when conducting foreign policy. That compromise was between Federalists such as George Washington (1732–1799) and John Adams (1735–1826), who wanted greater centralization of authority, and Anti-Federalists such as Thomas Jefferson (1743–1826), who favored placing power in the hands of ordinary individuals so that they can maximally manage their own affairs at the state and local levels.

The issue of individual states or regions protecting their own local territorial interests at the expense of national unity was not overcome with ratification of the Constitution, however. The Supreme Court under Chief Justice John Marshall (1755–1835) did much to establish and legitimate judicial review and to vigorously enforce the Constitution’s contract clause toward a vision of centralizing power in order to nourish economic growth through free market capitalism. Had this vision been successfully maintained into the future, prolonged federal dominance over states would have been established sooner rather than later in the course of U.S. national development. But that vision collapsed under Chief Justice Roger Brooke Taney (1777–1864). The Taney Court tolerated greater decentralization of the American political system (McCloskey 1994, chap. 4). The Court also wrongly and tragically tolerated slavery as a way of life in the South, as exemplified by its deplorable decision in Dred Scott v. Sandford (1857). Conflict over slavery (the placement of people, in this case black people, in bondage as the property of white owners) led to a secessionist push by southerners, culminating in a bloody civil war between armies from northern and southern states from 1861 to 1865. Federal dominance was more clearly established during the 1930s after President Franklin Delano Roosevelt (1882–1945) threatened to “pack” the Supreme Court with loyalists who would support and defend his New Deal policies, and the Court reversed its previous rejections of these policies.

Another characteristic of federalism is that the states provide plenty of opportunities to experiment with responses to public policy. As Justice Louis Brandeis (1856–1941) stated in his dissent in the 1932 case of New State Ice Co. v. Liebmann, “It is one of the happy incidents of the federal system that a single courageous state may, if its citizens choose, serve as a laboratory; and try novel social and economic experiments without risk to the rest of the country” (Ducat 2004, chap. 5). Those public policies that are chosen and implemented as a result of such experiments are afforded great legitimacy by the people who are most affected by them. But while this is a strong argument in favor of a federalist system, the crux of the argument in favor of federalism boils down to the expressed relationship between the application of governmental power and the preservation of individual freedom.

Under federalism, government power is decentralized and diffused among different levels and across different branches within the same level. Thus a third characteristic of federalism is that the diffusion of power afforded by such a system helps to preserve individual freedom and suppress tyranny, which is the systemic exploitation of the populace by a few self-serving individuals. Diffusion of power helps promote individual freedom because in smaller political units, individuals can participate more directly in a monolithic unitary government, and because individuals dissatisfied with conditions in one state can vote with their feet by moving to another state. But diffusion of power also suppresses tyranny, and it accomplishes this by minimizing the possibility that any one faction can gain enough access to government to push through any kind of policy that will exploit others without being detected. In addition, diffusion of power encourages coalition-building between individuals and groups operating at different levels of government in order to achieve public policy objectives.

But, generally speaking, there are some disadvantages to a federal system as well. Because federalism requires different institutions to approve a policy before it can be adopted, each decision point can unwittingly become a veto point that slows down the process of policymaking, or worse, prevents any action from being taken to resolve an important problem. Also, variation among states in their treatment of citizens, especially with respect to civil rights and liberties, can introduce a tension into the relationship between federalism and justice, which is thought to know no geographical boundaries.

**FEMALE-HEADED FAMILIES**

Families are constructed from primary social relationships, either by circumstance or choice. Scholars and legal experts have defined families as collections of individuals who are related by birth, adoption, or marriage. The sociologist Talcott Parsons set forth a conception of the family as a unit including a breadwinner husband and a homemaker wife. The economist Gary Becker examined the social and economic exchanges that take place among partners, bringing both benefits and costs. Social science definitions of families have become more inclusive of people unrelated by legal marriage who are closely connected or intimately involved, have mutual responsibilities and common interests, and who care for each other. Popular understandings of family tend to focus on how people feel about each other (love) and what people do for each other (commitment). As definitions of families have changed, family configurations have shifted as well. Families are increasingly headed by women and in such cases are commonly referred to as *female-headed*, *women-headed*, or *mother-headed* families. The terms *lone* mother and *single* mother typically refer to the same family structure in different countries. Women raising children in any of these families may be divorced, separated, single, never married, or in a cohabiting relationship with a male or female partner or if married may be living apart from their partner.

**WHY FAMILIES ARE CHANGING**

The demographic shift away from the “nuclear” family model consisting of two married heterosexual parents living together with biological children represents a major change in social relationships. Most agree that families look quite different in the early twenty-first century than they did a generation ago. Yet some argue that there was never a single dominant family pattern in Western society. Marriage patterns in the United States have been largely based on the different cultural and economic conditions facing African American and white women (Cherlin 1992). Historical discrimination toward racial and ethnic groups and blocked economic opportunities have depressed marriage rates overall and have contributed to increases in female-headed families. Social historians find that the high marital stability of the mid-twentieth-century United States is best described as an anomaly when compared to earlier decades and to later periods (Coontz 1992, 1997; Stacey 1990). Unmarried cohabitation has become both more prevalent and socially acceptable in all social classes since the 1970s. In Scandinavian countries cohabitation has been a long-standing pattern. Couples live together before marriage, in place of marriage, and in between marriages. Demographers and sociologists point out that cohabitation is an increasingly common context for childbearing and child rearing (Wu and Wolfe 2001).

Separating out the causes and consequences of changes in family structure is a challenge. One of many possible explanations is that shifts in values and norms have affected gender roles and expectations for marriage. Women's sexual independence and the decline in the number of “marriageable” men — those who are employed and stable — is yet another explanation for the decline of marriage. Increases in women's full-time employment, wages, and sustained commitment to the labor force are other hypotheses. Women may be earning enough to be able to choose independence over marriages to men who either cannot contribute economically or are difficult spouses. In such situations, women and men's lives may be less “complementary” (see Burns and Scott 1994). Some also argue that welfare supplanted wives' reliance on husbands for financial support, although welfare policies vary widely by region, country, and historical period.

Poverty scholars see a strong cross-national connection between female-headed families and poverty. In North America and western Europe, there is an increasing trend toward single-parent families. Men and women are marrying later, are increasingly choosing to cohabit rather than marry, and are increasingly likely to divorce. Out-of-wedlock childbearing is also increasing and is especially high among young African Americans and lowest among Latina women (Cherlin 1992; Wong, Garfinkel, and McLanahan 1993). In Central and South America legal marriage is normative, but mothers may leave children in the care of relatives to find work elsewhere temporarily or permanently. Globally, impoverished mothers earn money through legal or illegal (and risky and dangerous) means to support themselves and their children. Barbara Ehrenreich and Arlie Russell Hochschild (2002) point to the sexual and economic exploitation of women around the world.
Sociological research reflects serious concern about the growing numbers of female-headed families. Numerous studies conceptualize single motherhood as a social problem, either because of the social stigma attached to it or because of the feminization of poverty. Worldwide the majority of families headed by women are poor. In the United States female-headed families are three times more likely to be poor than are those in two-parent families. While quantitative research shows that many female-headed families are “at risk,” qualitative research focused on the meaning, arrangements, and flexibility of families headed by single women reveals that such arrangements can also bring greater stability compared to the existing alternatives.

COPING STRATEGIES AND FAMILY CHOICES

In the 1970s the anthropologist Carol Stack studied the kinship strategies of single women with children living in an urban housing project in the midwestern United States. She described a complex network of sharing and support among households. Similarly Kathryn Edin and Laura Lein (1997) found that poor single mothers rely on assistance from friends, relatives, and neighbors—both information and money to get through the month—whether they are working or receiving welfare payments.

Research has also explored how middle-class, single-mother families discuss their family circumstances, manage finances, and handle work and family responsibilities. Rosanna Hertz and Faith I. Ferguson (1997) found that the women they studied formed families without men for a number of different reasons, often related to childbearing—unexpected pregnancies, opportunities to adopt, anxiety about “biological clocks.” Some single women—heterosexual and lesbian—choose to adopt or become pregnant through donor insemination. These women were not opposed to nuclear family arrangements; they were actively seeking out partners and commitment while not rejecting the possibility of bearing and raising children alone. Margaret K. Nelson (2005) has examined the “social economy” of single motherhood in rural communities. Her emphasis on the combined importance of social networks and financial resources is particularly instructive for understanding the complexity of single mothers’ lives.

ECONOMIC CONSEQUENCES

The overall economic prognosis for single-mother families is bleak. Declining rates of marriage, increases in divorce, and the prevalence of out-of-wedlock childbearing means that a growing proportion of families with children are headed by a single parent for some period of time, and these households are much more likely to be poor. When fathers do not live with their children, they are much less likely to share in the financial costs of raising them. Single mothers bear most of the economic expenses and social responsibilities of child rearing. Low wages and high child-care costs contribute to the economic difficulties facing these households. Simply put, it costs more for single mothers to work, and many of the positions women hold do not pay enough to support their households or offer benefits that would help them or their children, like health care, vacations, or sick leave. Improving employment opportunities, strengthening the social welfare system, and increasing child support are all approaches that would contribute to the financial stability of female-headed families (McLanahan and Sandefur 1994; Edin and Lein 1997). The United Nations similarly points out that promoting gender equality and women’s empowerment is essential if the position of female-headed families is to be improved.

Involving parents who do not live with their children in their children’s lives may also be a way to ease the burdens experienced by one-parent families. Studies find that the overall workload at home of single mothers is much greater than that of married mothers. Single mothers spend more time on household tasks like cleaning and cooking as well as on the hands-on care of children. The work overload experienced by single mothers produces a great deal of stress and may affect parenting practices. It is unclear whether children receive more attention and supervision in two-parent or one-parent households. Nelson’s (2005) study shows that rural single mothers sometimes have difficulty arranging for tasks typically performed by men, like landscaping and automobile repairs. Henny M. W. Bos, Frank van Balen, and C. Dymphna van den Boom (2004) find that lesbian-mother families are no more or less disadvantaged than are heterosexual families.

A number of studies have suggested that there is a “wage penalty” for motherhood that does not exist for fatherhood. Losing time from work to raise young children brings a decline in earnings in the United States and western Europe. In many cultures and countries caregiving is exclusively women’s domain. The depressed education levels and limited work opportunities that result from this focus have negative economic repercussions for women. Michelle J. Budig and Paula England (2001) analyzed the characteristics of many different jobs—including female-dominated occupations—and found that wage penalties exist for all mothers. Divorced and married mothers experience higher child-related economic penalties than do never-married mothers, as do women with more than one child. However, the penalty for African American and Latina women with more than two children appears to be smaller than for others (Budig and England 2001). Some of the penalty, Budig and England maintain, is explained by work interruptions, changes to
part-time status, lack of seniority, and relatively limited work experience. The wage penalty for women is found across jobs that otherwise have different characteristics. It is for future researchers to determine whether employer discrimination is entirely responsible or whether reduced productivity at work accounts for some of the wage differences. Much research also remains to be done on the relationship between the female-headed family and women and children's poverty levels and on the question of family stability.

FEMININE MYSTIQUE

SEE Friedan, Betty.

FEMININITY

Femininity is commonly understood to refer to a collection of qualities or attributes associated with women in distinction from men, whose own qualities are signified by the antonym masculinity. Yet precisely what qualities qualify as feminine (or masculine) is subject to discussion and contention, as is whether such qualities should be considered innate traits or cultural norms. Passivity, submissiveness, and compassionate, caring, nurturing behavior toward others, especially infants, are widely considered feminine traits in comparison to masculine assertiveness and competitiveness. Their prevalence has lent credence to the belief that they are rooted in female biology and anatomy, whether by divine design or Darwinian natural selection. In the latter case, theory postulates higher rates of reproduction for passive women, who could most easily be sexually subdued, and higher survival rates for babies born to nurturing women. However, even the most widely shared so-called feminine traits are not universal, whether the comparison considers different cultures, different groups or individuals within a given society, or different periods of history. Since Margaret Mead's (1901–1978) groundbreaking anthropological study in 1936 first demonstrated cultural variability in behavior and temperament for both sexes, thus challenging previous presumptions about a universal feminine (or masculine) essential nature, much scholarly attention has been paid to how norms of gender may be socially and culturally constructed (Tarrant 2006).
**Femininity**

Women come to participate in upholding standards culturally deemed feminine for behavior and appearance through mechanisms of socialization that are multiple and not always obvious. Enforcement is the most obvious. Over the last few millennia of known human history, broadly influential cultural systems, such as the religions Judaism, Christianity, Islam, and Hinduism and the Confucian code of conduct, have explicitly directed that women's primary social duty is to be obedient wives and devoted mothers. Legal and paralegal structures derived from such religious and moral traditions have enforced these directives using punishments ranging from mild to extreme in severity depending on specific social and historical circumstances. Under the Taliban regime in Afghanistan at the beginning of the twenty-first century, for example, punishment for noncompliance with brutally extreme restrictions on women's appearance and behavior included public flogging and execution. Compulsion, however, is not the only or even necessarily the most effective means for encouraging women to subscribe to femininity norms. Social rewards and personal satisfaction are also motivators. Piety is its own reward for a woman of any faith who believes she is behaving in accordance with divine will. Depending on how she interprets her faith, a contemporary Muslim woman may thus signal her femininity and her piety by choosing to wear the veil whether she lives under a theocratic or a secular political system. Her choice to veil may be reinforced by additional rewards, such as greater respect and personal autonomy accorded to her by her family and the local Muslim community (Hoodfar 2003).

Marriage, in most cultures, has been the principal reward for successful displays of femininity. Under economic conditions in which family well-being is heavily dependent on women's domestic production, wifely assets tend to reside primarily in a woman's skill in the feminine activities of domestic labor. When a wife's domestic productivity is not essential, whether due to class privilege or to postindustrial economic structures that shift production away from the home, her feminine assets come to be measured instead through her appearance and character. Patriarchal cultural conditions prevalent in most, but not all, societies determine ideal feminine appearance and character traits to be those that make a woman sexually attractive to a man, most suitable to represent his social status, and most trustworthy to mother his children. Thus physical beauty, both natural and artificial, balanced by character traits of sexual modesty, nurturing kindness, and a strong sense of duty to family have become widespread hallmarks of ideal femininity. But although women can derive personal satisfaction in meeting such measures, the accompanying price has often been problematic. Ironically, the sufferings of many upper-class women most palpably illustrate the point. Beauty norms that emerged in stratified societies to simultaneously signal high social status sometimes entailed not just delicacy, refinement, and taste in adornment but actual physical fragility, frailty, even incapacity as symbols of the socioeconomic status of the husband, proving his wealth sufficient to support a wife whose physical labor was not necessary. The former practices of Chinese foot binding and European waist cinching illustrate the debilitating operations of such elite-class norms of feminine beauty. Although they were believed to enhance a woman's erotic appeal (while simultaneously symbolizing her sexual restraint), they also hobbled or otherwise constrained her physical capacity, not to mention causing her discomfort and pain.

Less self-evident forms of harm, whether through conformity to feminine ideals or through disqualification from femininity by social status, sexual orientation, or race, among other factors, as well as more nuanced sociological interpretations of incentives for feminine performances, are topics that have generated considerable theorizing across scholarly disciplines (Brownmiller 1984; Bartky 1990; Martin 1996; Skeggs 1998; Lee 2000; Burns-Ardolino 2003; Taylor 2003; Bathla 2004). The philosopher Simone de Beauvoir (1908–1986) is often quoted for her ideas about how the sense of self that conformity to ideals of femininity creates in women is a sense of self as “Other,” existing only in secondary relation to the primary “Self,” the fully human self that in patriarchal traditions can only be claimed by men.

Psychologists have explored how the expectation to nurture others has led legions of women to psychologically unhealthy degrees of self-sacrifice, labeled a “negative feminine trait” in the literature. Many scholars have written about how women effectively create themselves as objects, rather than subjects, in their pursuit of feminine beauty norms yet are bound not only to fail in this pursuit but also to be reminded of their failure incessantly and distracted repeatedly by promises for new ways to succeed. Pervasive modern mass media and capitalist commerce promulgate a beauty regime that harshly judges the femininity of women whose age, skin color, hair texture, physique type, or fashion sense do not match the dominant cultural ideal, then exploits feelings of inadequacy to sell beauty products and services from lipstick to skin lightener to liposuction and breast augmentation in order to turn a profit at their expense. This beauty regime thoroughly ensnares as well. Fashion is ever changing, but whatever the fashion, every detail of the body demands proper attention. Each minutiae of how a woman's body looks, feels, and smells, how it is clothed, coiffed, enhanced with makeup and other adornment, even how it speaks and moves or rests combines to express normative femininity successfully or not. Enormous ceaseless efforts of self-surveillance and self-discipline are required from an early age to produce the modern feminine body. A self-
policing gendered identity also develops through this process. This form of feminine subjectivity is interpreted by some theorists as being more completely subjected to modern versions of patriarchal power than is possible under crude enforcement or injurious restraint which, albeit brutal techniques of control, are less thoroughly invasive of the whole being.

Critics of the physical, psychological, economic, and political harms resulting from socialization processes aimed at patriarchal ideals of femininity draw encouragement from the historic appearance of alternate ideals and socialization opportunities available to girls following the women's movements of the modern era. Competitive assertiveness, physical strength, and even masculinity are developed in the characters and bodies of girls and women who engage in amateur and professional sports, for example (Boyle 2005; Koca and Asci 2005; Kindlon 2006). Furthermore the representation of these athletes in mass media amplifies the scope of qualities that femininity is seen to signify culturally, stretching the meaning to incorporate qualities previously considered exclusively masculine (Carty 2005). Some critics of patriarchal femininity see reason to hope that social developments blurring traditional gender roles, such as women in sports, or politics, or the military, will help move common understanding of femininity beyond the still dominant, but demonstrably deleterious, dualistic framework in which femininity and masculinity are conceived as mutually exclusive opposites.

FEMINISM

Feminism refers to social theories, economic ideologies, political movements, and moral philosophies aimed at bringing equality to women. Feminism has been identified with different groups and different issues over the course of its history. The first wave gave rise to liberal feminists, who fought for the right to vote, access to education, and marriage law reforms in the 1800s and early 1900s. The second wave witnessed the emergence of radical feminists, who protested for work and reproductive rights in the 1960s and 1970s. The numerous feminist groups concerned with all forms of oppression (e.g., racism, classism) evolved as the third wave in the 1990s.

ORIGINS OF FEMINISM

The desire for equality predates the existence of the term feminism or the movement it has come to represent. The term feminism comes from the French word féminisme and was popularized by Hubertine Auclert in 1882 when she organized the first women's suffragist society in France. However, prior to the advent of the word, there were publications that fell within the purview of feminism. One of the first, by the medieval French poet Christine de Pizan, was Livre de la cité des dames (1405; The Book of the City
of Ladies, 1999), in which Pizan suggests that women should build their own cities, free of men, so as to avoid men's violence and oppression. Dealing more specifically with rights, John Locke's Two Treatises of Government (1690) argued that all individuals have indelible natural rights to life, liberty, and possessions, which no government can deny.

Locke's work inspired Mary Wollstonecraft's Vindication of the Rights of Women (1792), one of the first feminist manifestos. Wollstonecraft argued that women were human beings who should not be denied the same individual rights as men because of their sex. She advocated that women be viewed as equal to men under the law, with all the same rights and privileges, including the right to education, earnings, and property ownership. The rights of women were further advocated by John Stuart Mill in his treatise The Subjection of Women (1869). Mill contended that women should be granted the same rights and privileges as men under the law. In 1866, during his term as a member of Parliament for Westminster, Mill introduced a motion to enfranchise women on the grounds that taxpayers should have representation. The motion was defeated (196 to 73 votes), but the impetus for women's suffrage was not. The right to vote and the right to a proper education were two primary concerns that propelled the first of the three waves of the feminist movement.

THE FIRST WAVE OF FEMINISM
The period from the mid-nineteenth century to the early twentieth century saw tremendous activity for the women's movement. Key concerns included improvements in education, employment, and marriage laws. In much of North America and Europe, the right to higher education provided the movement's initial spark. In other nations, cultural and religious constrictions such as suttee (self-immolation by Hindu widows), purdah (isolation of women, shielding them from public view), child marriage, and foot binding provided the initial focus for reform. In England and the United States in the 1800s (dates vary by state), marital laws were reformed with the passage of married women's property acts, which enabled wives to own property, enter into contractual agreements, sue, and be sued. However, in many countries it became apparent that the right to vote was instrumental in obtaining other reforms, so voting became the focus of the movement.

In the United States the first women's rights convention was held in Seneca Falls, New York, in 1848. In 1869 Elizabeth Cady Stanton and Susan B. Anthony founded the National Woman Suffrage Association and demanded not just the right to vote but marital reform as well. The exclusion of male members and the request for marital reform, instead of focusing solely on the vote, was frowned upon by some (e.g., Lucy Stone and Henry Blackwell), resulting in the creation of the American Women Suffrage Association. However, the two groups merged in 1890. Women in New Zealand were among the first to obtain the right to vote (1893), and other countries quickly followed. For example, women's suffrage was achieved in Australia in 1902, Finland in 1906, Denmark in 1915, Russia in 1917, Czechoslovakia, England, and Germany in 1918, the Netherlands and Sweden in 1919, and the United States in 1920.

In many countries, after winning the right to vote, women turned their attention to education and employment rights. Upon achieving greater educational and employment access, women entered both of these spheres in record numbers. However, this newfound freedom was quickly tempered by the Great Depression. Although the effects of the Depression were felt at different times in different countries, the 1930s saw immobilization in the feminist movement. During this period, women were discouraged from seeking employment because of the scarcity of jobs. This employment hiatus was quickly reversed with the start of World War II in 1939, as women were encouraged to fill voids in a number of professions previously closed to them (e.g., factory workers, pilots) because so many men were sent to battle. Women proved to be effective workers, but they were nonetheless displaced by returning soldiers at the war's end.

The tumultuousness of the war years was followed by a period of relative calm, during which the movement waned. However, having tasted independence, career options, and good pay, women were no longer content to be housewives. The publication of Simone de Beauvoir's Le deuxième sexe in 1949 (The Second Sex; English trans., 1953) reminded women that there was still much work to be done. This period of tranquility soon ended in the 1960s with the start of the second wave of the feminist movement.

THE SECOND WAVE OF FEMINISM
The term second wave was coined by Martha Lear and refers to the feminist movement that began in the 1960s. The leading issues were demands for employment and reproductive rights. In the United States the second wave rose out of the civil rights and anti-Vietnam War movements. Even within these "pro-rights" organizations, women were relegated to second-class status. In an effort to gain a voice, two branches of the feminist movement emerged: the women's liberation movement (WLM) and the National Organization for Women (NOW). The WLM evolved out of the New Left and encompassed more loosely organized radical groups that formed following their exclusion from other New Left politics. They gained great notoriety in 1968, when they demonstrated
against the Miss America pageant for its sexist objectification of women. NOW was a more structured, liberal group founded in 1966 by Betty Friedan, Aileen Hernandez, Pauli Murray, and others. Although NOW grew to become more inclusive, in 1968 Ti-Grace Atkinson left it and created her own group, the Feminists, to protest NOW’s hierarchical structure. NOW also lost members because of its pro-choice stance; some conservative women, led by Elizabeth Boyer, left the organization and created the Women’s Equity Action League. In spite of these early setbacks, NOW grew to become the largest women’s organization in the United States and championed the equal rights amendment (ERA) as its primary cause. Despite approval by the U.S. House and Senate, the ERA was not ratified by the requisite thirty-eight states by the 1982 deadline.

This period was marked by a number of historic events, including the 1963 Commission on the Status of Women report that documented discrimination against women in all facets of life. The pervasiveness of discrimination was also the topic of Betty Friedan’s best-selling book *The Feminine Mystique* (1963). These two documents invigorated the women’s rights movement, and its activities were instrumental in bringing about changes. In 1963 Congress passed the Equal Pay Act, which prohibited unequal pay for equal work. In 1964 Congress passed Title VII of the Civil Rights Act, which prohibited employment discrimination on the basis of sex, race, color, religion, and national origin. Ironically, the inclusion of “sex” was actually a last-minute attempt to kill the bill, but it passed anyway. Prohibitions against sexual discrimination were further extended in 1972 with the passage of Title IX of the Education Amendment, which prohibited discrimination in educational settings. In 1973 the U.S. Supreme Court’s decision in *Roe v. Wade* struck down state laws restricting a women’s right to an abortion, thereby legalizing it in all fifty states.

In addition to employment and reproduction rights, concerns about pornography and sexuality more generally also came to the fore. However, there was little consensus on these issues, and this disagreement culminated in what is termed the feminist sex wars. The sex wars of the 1980s were between antipornography feminists (e.g., Catherine MacKinnon, Andrea Dworkin, and Robin Morgan), who argued that pornography degrades and promotes violence against women, and sex-positive feminists (e.g., Camille Paglia, Ellen Willis, and Gayle Rubin), who opposed limiting sexual expression. This conflict, along with the fact that many feminists felt that other sources of oppression, such as race and class, were being neglected, caused the already multipartite movement to become increasingly fractured, resulting in the birth of third-wave feminism.

**THE THIRD WAVE OF FEMINISM**

Third-wave feminism evolved out of the disillusionment of many feminists with the overemphasis on the experience of middle-class white women in the mainstream. Feminists of color (e.g., Gloria Anzaldúa, bell hooks, Chela Sandóval, Cherrie Moraga, Audre Lorde, and Maxine Hong Kingston) emphasized the significance of race, class, sexual orientation, and other socially structured forms of bias on women’s lives (Kinser 2004). Critical race theorist and law professor Kimberlé W. Crenshaw introduced the term *intersectionalities* to highlight the multiplicative effect of these different sites of oppression. Counter to postfeminist contentions that feminism was obsolete as women had gained equality, third-wavers contended that there was still work to be done, specifically related to the “micropolitics” of gender oppression.

The term *third-wave feminist* was popularized by the 1992 *Ms.* magazine article titled “Becoming the Third Wave” by Rebecca Walker, who stated: “I am not a post-feminism feminist. I am the third wave” (Walker 1992, p. 40). In her article Walker describes her rage over the outcome of the Clarence Thomas hearings (in which Anita Hill testified that Thomas had sexually harassed her; Thomas was confirmed as a Supreme Court justice, while Hill was repudiated) and her subsequent commitment to feminism. Walker’s article generated a large response from young women, who indicated that they have not given up the cause but are feminists in their own way. That is, they embrace a more pluralistic definition of feminism; they are concerned with the intersectionalities of oppression and the impact of globalism, technology, and other forces, and they operate on a more grassroots level (Kinser 2004).

Although both second- and third-wave feminists are still at work, their divergent concerns spawned different groups, including black feminists, critical feminists, and global feminists.

**TYPES OF FEMINISM**

Although there are many types of feminism, the four most common are liberal, radical, Marxist, and socialist. What differentiates them is the degree to which they accept that the different social structures in power are responsible for oppression. Liberal feminism, considered the most mainstream, accepts that sex differences exist but contends that social, legal, and economic opportunities should be equal for men and women. Liberal feminists are concerned with individual rights and promoting change through legal and legislative means while still operating within the current patriarchal structure.

Radical feminism emerged from the ideals of the New Left and the women’s liberation movement in the late 1960s. Radical feminists argue that men are the
oppressors of women and that the patriarchal social structure must be replaced for women to gain equality. The term radical feminism is used to represent many divergent groups, including cultural feminism, lesbian feminism, and revolutionary feminism.

Marxist feminists believe that women’s oppression stems largely from economic stratification brought about by the production methods inherent in capitalism. Accordingly, capitalism must be destroyed in order to emancipate women both as workers and as property within the marital sphere.

Drawing from both radical and Marxist ideologies, socialist feminists argue that both class and sexism are sources of women’s oppression. They advocate the end of capitalist patriarchy to reduce all forms of exploitation, as they are also concerned with oppression resulting from race, age, religion, and the like. In contrast to liberal feminism’s emphasis on individual rights, socialist feminists emphasize the social existence in the broader community.

IMPACT OF FEMINISM

In addition to voting, property, employment, and other rights, the women’s movement has also promoted other changes. For instance, not only do women have the right to vote but a number of countries have had female political leaders, including Chile, Finland, Ireland, Israel, Liberia, and Switzerland. In addition access to education has brought about a large increase in the number of women students, such that women now outnumber men in many nations’ schools. With regard to language, feminism has been influential in advancing the use of nonsexist terms (e.g., humankind in lieu of mankind). It has also had a tremendous impact on the institution of marriage, in terms not only of whether women marry but also whom they choose to marry (a man or a woman), as well as the distribution of familial labor within the marital union. Moreover following the lead of the nineteenth-century suffragist Lucy Stone, many women now maintain their maiden names after marriage. The movement has also influenced religion, with many liberal denominations now ordaining women. Feminist thinking has also influenced the social sciences. It is no longer acceptable to collect data solely on men and to apply the findings to women, because there are often important gender differences—for example, personality (Chodorow 1978).

Further, feminist researchers advocate increased use of qualitative methods in which participants play a greater role in informing the definition and measurement of the phenomenon under study.

FEMINISM, SECOND WAVE

Second Wave feminism applies to the women’s movement that began at the end of 1963 and extended into the 1980s. First Wave feminism addressed employment, mar-
riage laws, and education and later came to embrace the voting rights movement. Second Wave feminists went further to address the issues of equality of the sexes in the workplace, a woman's right to choose, feminine sexuality, and a furthering of political action to bring women's issues in a patriarchal society to light.

The starting point of the Second Wave is usually considered to be a 1963 report from the Committee on the Status of Women (CSW), which was begun by First Lady Eleanor Roosevelt and which she chaired until her death in 1962. The committee found that women were not being treated equally in the workplace and recommended mandatory fair hiring and pay, maternity leave for mothers, and affordable child care. Based on these recommendations, the Equal Pay Act was passed by Congress on June 10, 1963, making it illegal to pay women less for doing the same jobs as men.

Yet the women's movement at that time was relatively quiet. Most women were locked into traditional roles of wife, mother, nurse, teacher, secretary, and other “feminine” activities without the possibility of individual advancement or achievement. Then Betty Friedan, a New Jersey work-at-home journalist and mother, wrote *The Feminine Mystique* (1963) and her words sparked many more women into realizing that they wanted the freedom to control their own destinies. Friedan wrote about her own life and the frustrations that many other women were feeling about patriarchal attitudes regarding their roles. She equated American women with the inmates of Nazi concentration camps and evoked strong emotions in men and women, both pro and con. The book became a best seller, and the battle for equality of the sexes was rekindled.

A major milestone in the women's movement was the passage of Title VII of the Civil Rights Act of 1964, which made gender and racial discrimination in the workplace illegal. At the same time, the Equal Employment Opportunity Commission (EEOC) was established to investigate complaints and impose penalties on those not acting in accordance with the law. Title VII meant that women no longer would have to resign themselves to working as nurses or secretaries because they could not get into medical school or become business executives, though the atmosphere was slow to change.

In 1966, at the Third National Conference of the Commission on the Status of Women, a new organization was formed. Friedan was furious over the government's failure to enforce Title VII, and she invited a few women from the conference to her hotel room. She wanted to discuss stronger options than merely passing a resolution to recommend enforcement, and the women at the meeting decided instead to form their own organization, dedicated to the attainment of full equality for women. Friedan christened it the National Organization of Women (NOW) and the group drafted a statement of purpose.

In March 1969 New York journalist Gloria Steinem realized that the women's movement was not just for unhappy housewives when she attended a rally to “speak out” on abortion. It had been organized by the newly formed radical feminist group the Redstockings, and the meeting was standing room only. As women spoke about their own bad experiences, Steinem realized that she had felt the same anxieties over having had an abortion herself, and she identified with them. She immediately assumed responsibility in the cause of a woman's right to choose.

Steinem traveled around the country with a speaking partner, usually a woman of color, to address those who thought the movement was only for white middle-class women. The pair encouraged all women to understand their rights and to take part in the movement to demand them.

Where Friedan had been considered the founder of the Second Wave movement, Steinem was certainly its messenger. One of her early appearances was in testifying before a Senate subcommittee on the Equal Rights Amendment (ERA), and in 1971 Steinem used her journalistic connections to publish the first edition of *Ms.* magazine as a supplement to *New York Magazine*. In eight days, all 300,000 printed copies were sold. *Ms.* became the premiere forum for feminist issues and Steinem became a feminist icon.

Her testimony and that of other women helped put pressure on Congress to pass the ERA in 1972. The law was to be simple, as written by Alice Paul in 1923: “Equality of rights under the law shall not be denied or abridged by the United States or by any State on account of sex.” Yet there was still a long battle, as the ERA had to be sent to all 50 states for ratification, and 38 would have to pass it before it would become law.

Legal wheels did not stop turning. Title XI of the Education Amendments banned sexual discrimination in schools, and the greatest victory was a result of the Supreme Court decision in the case of *Roe v. Wade* in 1973, making abortion in the first trimester of pregnancy legal. The first national convention of the National Women's Political Caucus was also held that year, as women became a force in national politics. Anne Armstrong, the first woman to hold a cabinet-level position, also became the first woman to make the keynote speech at the Republican National Convention.

The end of the Second Wave feminist movement is often seen as occurring sometime in the 1980s up to the 1990s when Third Wave feminism sprouted from an article written by Rebecca Walker, titled “Becoming the Third Wave,” in *Ms.* in January 1992. The renewed emphasis of this movement is to expand definitions of gender and
sexuality, race, and class. Many in this group are disappointed that the Second Wave did not fully achieve their ideals, and this was punctuated by the failure of the ERA to be ratified by the required 38 states, though ratification is still being pursued into the twenty-first century.

However, some view feminist advancement as the cause of many societal ills. The concept of women working outside the home has become a necessity for most families, leaving children to be raised by caregivers rather than parents. Many see the decline of the family in America as a result. The openness with which homosexuality and homosexual marriage is approached in today's society seems even more threatening to those with traditional values. However, most men and women working in the area of civil rights maintain that equality—regardless of race, creed, sexual orientation, or mental or physical ability—is a natural right. Feminist movements will undoubtedly continue in various forms until this ideal has been reached.

FENNO, RICHARD F., JR.
1926–

The contributions of Richard F. Fenno Jr. to the political science world are many and varied. His work on Congress and the actions of legislators has pioneered fields of study in political science.

After studying at Amherst and Harvard, Fenno published his doctoral dissertation as his first book in 1959. An article on the House appropriations committee (1962) and a book, The Power of the Purse: Appropriation Politics in Congress (1966), soon followed. Although outdated by changes in Congress, Fenno's conceptualization of the power struggles, structures, and behavior of representatives have formed the basic vocabulary used in legislative studies.

In 1973 Fenno published Congressmen in Committees, which explores whether committees matter in Congress, and what role they play in fulfilling individual ambitions of congressmen. Fenno's next work, Home Style: House Members in Their Districts (1978), studies how representatives behave while at home in their districts. In Home Style, Fenno pioneered the "soaking and poking" method of social science research on politicians, in which the researcher follows the subject through the field, observing and documenting behavior. These works demonstrate the researcher's commitment to presenting politicians as necessary elements in the political world, whose actions are worth examination. This stance, which often separates Fenno from others in the field, has led to interesting discoveries about the nature of politicians and the political world. These works have also garnered criticism, as Fenno's research required him to develop friendships with his subjects, raising doubts about his level of objectivity. Other critics have charged that Fenno's observational studies are invalid, because his presence may affect the behavior of the representatives, and because those representatives that consent to be studied may not be an accurate sample of representatives as a whole. Furthermore, the very nature of participant-observer studies requires that only a small number of politicians is studied, thus decreasing the generalizability of any theory arising from the work. Fenno has responded to these criticisms by defending his work as purely exploratory in nature.

Fenno has been president of the American Political Science Association, is a member of the National Academy of Sciences, and a fellow of the American Academy of Arts and Sciences. He is a distinguished pro-
Fertile Crescent

The term Fertile Crescent refers to part of the ancient Near East that has been considered to be the principal center for the emergence of agriculture, villages, and cities, and hence the “cradle of civilization.” The term was coined and popularized by James Henry Breasted (1865–1935), a scholar of ancient Egypt and director of the Oriental Institute at the University of Chicago, in his 1916 textbook for high school students, Ancient Times: A History of the Early World. As originally designated by Breasted, the Fertile Crescent is an arc or semicircle that included the relatively well-watered hilly areas of Palestine and Lebanon/western Syria (the Levant) on the west, stretching across northern Syria at the foot of the highland plateau of Anatolia, and then southward, east of the Tigris River to the foot of the Zagros Mountains in Iraq and Iran, ending in the alluvial plain created by the Tigris and Euphrates rivers southeast of contemporary Baghdad. As envisioned by Breasted, the Fertile Crescent’s arc surrounded hostile desert and acted as a fertile shore against this “Desert Bay” (the Syrian Desert). The first “ancient civilizations” emerged from this region, including the Sumerians at the head of the Persian Gulf; the Akkadians, Babylonians, and Assyrians in Mesopotamia (Iraq) between the two great rivers; and, at a later period, the Phoenicians on the west. Many of the earliest settlements and cities of the ancient world are found within this arc. The Fertile Crescent is sometimes mentioned in conjunction with ancient Egypt, since it is one of the first civilizations as well. In popular usage, the Fertile Crescent sometimes even incorporates ancient Egypt of the Nile Valley, although scholars have never accepted this wider usage. Many works on the archaeology or the lands of the Bible have also used the term Fertile Crescent (e.g., Magnusson 1977).

Besides being designated as the cradle of civilization, the Fertile Crescent has been postulated as the key area for the earlier Neolithic Revolution, the beginnings of agriculture and farming on the more generously rain-fed outer margins of the arc. In fact, whereas Breasted formulated the term mainly for the beginnings of cities and “civilization,” its usage for the region of the emergence of agriculture and villages has been much more common. Robert Braidwood’s (1907–2003) excavations from 1948 to 1955 at Jarmo, a site in northeastern Iraq in the foothills of the Zagros Mountains, began to provide botanical evidence for the first plant domestication occurring in the “hilly flanks,” and subsequent work has shown that the Fertile Crescent was indeed a focus for plant and animal domestication. Within this arc are found some of the earliest examples for the “founder crops” (Zohary 1996), such as the domesticated cereals of barley, emmer wheat, and einkorn wheat; the pulses of peas, chickpeas, lentils, and bitter vetch; and flax used as a fiber. Domesticated animals included goats, sheep, pigs, and cattle. The first evidence of cultivated crops begin to appear about 9000 BCE in the Levant, and by 6000 BCE villages, the farming of plants, and the use of domesticated animals were well established in many parts of the Fertile Crescent (and beyond in a few places). Horticulture began mainly in the Levant during the Chalcolithic period (5000–3500 BCE), which first focused on growing olives, figs, pomegranates, grapes, and dates (the latter perhaps first cultivated in other areas of the Near East). This core area for the Neolithic Revolution is somewhat larger than Breasted’s original concept. The argument for the Fertile Crescent’s central role has been popularized, for instance, by geographer and physiologist Jared Diamond in Guns, Germs, and Steel (1997), where he advocates the significance of the Mediterranean climate (wet winters, dry summers) and that most of the major plants and animals that were genetically and behaviorally predisposed to domestication were found basically together in parts of this arc. Diamond’s rather generalized argument for the Fertile Crescent extends more northward onto the Anatolian Plateau and includes a tongue that stretches westward to incorporate the significant circa 6000 BCE site of Çatal Hüyük on the Konya Plain in central Anatolia.

The name Fertile Crescent has been criticized for not being a proper term or even a relevant concept. In William Hallo and William Simpson’s 1998 edition of their textbook, The Ancient Near East: A History, they take the term to task, asserting that, in fact, the arc of the Fertile Crescent was not the area for the beginnings of...
agriculture (and the Neolithic Revolution), and that evidence now shows the origins to be also in highland areas, such as Anatolia, with greater rainfall and native vegetation. They (and others) also stress that many of the “civilizations” and cities that emerged in Mesopotamia could do so only after developing extensive irrigation systems (and hence these areas were not in a “fertile” region). On the other hand, different terms being proposed by some Near Eastern archaeologists also often refer to a semicircle for origins of agriculture and the emergence of cities, and actually cover a region similar to the Fertile Crescent, using such names as Near Eastern nuclear arc (Harlan 1977), Zagrosian arc (Maisels 1990), Zagros-Kurdi-Taurus mountain arc (Maisels 1990), or the Near East arc (Zohary and Hopf 1988). That many sites for early plant and animal domestication lie outside the Fertile Crescent may not necessarily entirely negate the importance of this core region for the beginnings of agriculture and farming, although further discoveries in Anatolia, Iran, and other areas (including India or China) may require significant reinterpretations or refinements in the future.

Following World War II (1939–1945), the use of the term Fertile Crescent became particularly popular in other fields besides ancient Near Eastern studies and archaeology. Some historians began to refer to the Arab countries (or previous mandates) of Syria, Iraq, and Lebanon as the Fertile Crescent. For example, in 1966 P. M. Holt published a political history entitled Egypt and the Fertile Crescent: 1516–1922, while the economist Charles Issawi (1916–2000), as one of his several books of translated documents, published The Fertile Crescent, 1800–1914 (1988), in which all the chapters focus on either Iraq or Syria (with Lebanon sometimes included as part of the latter). H. G. Balfour-Paul, writing on “Fertile Crescent Unity Plans” (1996), discusses the various schemes to unite the Arabs of Iraq and Syria (and Lebanon) after World War I (1914–1918), yet the term Fertile Crescent was not used by the individuals and groups involved in these discussions; the use of Fertile Crescent for these unity plans is entirely artificially imposed.

At the beginning of the twenty-first century, historians, political scientists, and others who deal with the contemporary Arab world and Middle East seldom use the term Fertile Crescent for the countries of the Levant. Scholars of the ancient Near East also generally refrain from using the term. Yet, the Fertile Crescent, as a simple explanation for the origins of agriculture, villages, cities, and “civilization,” is still used widely in the more popular literature, and with its long use by scholars in the past and its prominence in such works as Guns, Germs, and Steel, it is not a concept that will easily disappear from the literature or the imagination.

FERTILITY, HUMAN

The term fertility refers to the actual production of children. It may be distinguished from fecundity, which is the capability to produce children. Demographers make this important distinction, but not all scientists do. Medical scientists, for instance, use the term fertility to refer to reproductive ability. Also, the meaning of the terms of fertility and fecundity are reversed among French-speaking and Spanish-speaking demographers. They too distin-
guish between the potential and actual production of children. But French-speaking demographers use the term *fertilité*, and Spanish-speaking demographers the term *fecundidad*, to refer to reproductive ability, and *fecundité* and *fecundidad*, respectively, to refer to actual reproductive performance.

One of the most popular and easily understood and interpreted methods for quantifying fertility is the crude birth rate (CBR), that is, the number of births in a population in a given year, per one thousand members of the population, expressed as follows:

$$\text{CBR} = \frac{\text{births in the year}}{\text{population at mid-year}} \times 1,000$$

Using 2005 data for China (Population Reference Bureau 2005), the equation becomes:

$$\text{CBR} = \frac{15,637,000}{1,303,700,000} \times 1,000 = 12$$

This means that in China in 2005, there were twelve babies born for every thousand persons in the population. Crude birth rates among the countries of the world in 2005 ranged from lows of nine in several countries, including Japan, Germany, Bulgaria, Poland, Italy, Hungary, and Greece, to highs of fifty-six in Niger and fifty in Liberia, Mali, Malawi, and Guinea-Bissau (Population Reference Bureau 2005). The range of crude birth rates is much greater than that for crude death rates, which in 2005 extended from a low of one in the United Arab Emirates to a high of twenty-eight in Botswana and Lesotho.

Lay persons employ the CBR more often than any other fertility measure, but it is not the most accurate of the measures. The CBR's denominator does not truly represent the population for which the possibility of giving birth is an issue because it includes males, prepuberty females, and postmenopausal females. Demographers refer to the population in the denominator as the “risk population.” Because of this overly inclusive denominator, the CBR should be interpreted with caution.

Demographers use more refined fertility measures, including the general fertility rate (GFR), age-specific fertility rates (ASFR), the total fertility rate (TFR), the gross reproduction rate (GRR), and the net reproduction rate (NRR). The GFR, ASFR, and TFR are increasingly more accurate measures of the childbearing experiences of a population. The GRR and the NRR measure not fertility but reproduction, that is, the production of females (Rowland 2003).

Fecundity can be divided into five categories on the basis of the extent of fecundity impairment and the degree of certainty regarding this impairment. Badenhorst and Higgins (1962, p. 281) note that all couples may be classified as either *fecund* or *sub-fecund*; the latter may be subdivided into the following groups: *definitely sterile, probably sterile, semi-fecund, and fecundity indeterminate*. Badenhorst and Higgins define the *sub-fecund* groups as follows: *definitely sterile* couples are those “for whom conception is impossible because of certain physical or medical conditions, including an operation or other physical impairment or menopause”; *probably sterile* couples are those “for whom a birth is improbable on the basis of specific medical evidence”; *semi-fecund* couples are those who have married or cohabited for a relatively long time without using contraception but have not conceived; *fecundity indeterminate* couples are those who meet the criteria for semi-fecund couples, “except that the wife sometimes reported douching ‘for cleanliness only’ soon after intercourse” (that is, a form of contraception is used). These couples are defined as *fecundity indeterminate* because they could be potentially fecund and some of them are observed to be fecund as well (Badenhorst and Higgins 1962). Demographic research has shown that the majority of sub-fecund couples are impaired according to one of the above definitions.

As for fertility, demographers have conducted extensive studies examining its trends and determinants. It has been found that during the past few decades, fertility in most countries of the world is in a declining pattern, and this is particularly the case in the more industrialized countries. Beginning in the 1990s, fertility below the replacement level of 2.1 children per woman (as measured using the total fertility rate) has emerged in many countries of the world (Kohler et al. 2002, Morgan 2003). Among the 205 countries worldwide (a country is defined here as a territory with at least 150,000 population), 73 had fertility rates at or below the replacement level in 2005. Following Billari (2004), we refer to fertility as being “low” when the TFR is below the replacement level of 2.1, as being “very low” when it is below 1.5, and as being “lowest low” when it is below 1.3. In 2005, eleven countries reported “lowest low” fertility, that is, a fertility rate below 1.3; these countries include South Korea, Taiwan, Poland, the Czech Republic, Slovakia, and Ukraine.

A number of theories have been proposed to explain the dynamics of fertility. Prominent explanations include proximate determinants theory (Bongaarts, 1994), demographic transition theory (Notestein 1945, Thompson 1929, Davis 1963, Hirschman 1994, Knodel and van de Walle 1979, Poston 2000), wealth flows theory (Caldwell 1976), human ecological theory (Browning and Poston 1980, Kasarda 1971, Poston and Frisbie 2005, London 1987, London and Hadden 1989), political economic theory (Greenhalgh 1990, Kertzer and Hogan 1989), and diffusion theory (Coale and Watkins 1986). Many of these theories use proximate determinants of fertility (pro-
portion married, contraception use, induced abortion, and duration of fertility period) and other social, economic, ecological, political, and cultural factors to understand the dynamics of fertility change.

One limitation of the above fertility measures and theories is that they are usually derived from calculations and analyses only of females. The fertility of men and the determinants of male fertility are rarely examined and compared with those of females. Males are a neglected minority in fertility studies. Several reasons have been proposed to justify this exclusion. Some biological reasons are that the fecundity, and the childbearing years of women occur in a more sharply defined and narrower range (fifteen to forty-nine) than they do for men (fifteen to seventy-nine). In addition, “both the spacing and number of children are less subject to variation among women; a woman can have children only at intervals of 1 or 2 years, whereas a man can have hundreds” (Keyfitz 1977, p. 114). Some methodological justifications are that data on parental age at the birth of a child are more frequently collected on birth registration certificates for the mothers than for the fathers. When such data are obtained for mothers and fathers, there are a greater number of instances of unreported age data for fathers, and this is especially the situation for births occurring outside marriage. The sociological reasons include the fact that men have been regarded principally as breadwinners and “as typically uninvolved in fertility except to impregnate women and to stand in the way of their contraceptive use” (Greene and Biddlecom 2000, p. 83).

However, biological and demographic studies provide evidence that men are important to fertility outcomes and related behaviors. Considering mammalian species in general, Coleman indicates that “the male sex as a whole contributes an equivalent amount of genetic information to the next generation as the female, but the variance contributed by that of males to the next generation in many species—especially those which practice polygamy—is considerably greater than that of the female sex” (p. 33). That is, most females reproduce, some males do not reproduce, and other males have a large amount of offspring. In addition, biologists have found there are more childless males than childless females in many species (Coleman 2000).

Demographically, it has been shown that men have different patterns of fertility and fertility-related behavior. For men, age-specific fertility tends to start later, stops much later, and remains higher than that of women (Paget and Timaeus 1994). The total fertility rates (TFRs) for males and females also differ. Results show that in most industrialized countries male TFRs were historically higher than female TFRs. Over time this gap narrowed and eventually a crossover occurred between these rates.

This means that men and women who conformed to the sex- and age-specific fertility rates of an area at one point in time and had less than 2.2 children during their childbearing years were more likely to have similar than dissimilar fertility (Zhang 2007; Coleman 2000; also see Smith 1992, and Myers 1941).

The special importance of men is also seen in determinants of fertility and fertility-related behaviors such as cohabitation, marriage, and employment. Whereas the focus has been on women’s fertility, in the United States it is men’s fertility that is more likely to be influenced by marital and employment status. Being ever married and ever working significantly increases men’s number of children ever born (CEB), whereas such factors do not have as strong of an impact on women, despite the frequent emphasis on the relevance of labor force participation for women’s fertility (Zhang 2007). Research using various independent variables from several fertility paradigms—namely, human ecology, political economy, and wealth flows—to predict both male and female TFRs for the counties of Taiwan has shown that the variables have consistently performed better in predicting variation in female TFRs than in male TFRs (Zhang 2007).

Men also have different cohabitation and marriage patterns from women. In the United States, for birth cohorts born between 1958 and 1987, it has been shown that living alone, being foreign-born, and living in fragmented families increase the odds of cohabitation for women but not for men. Foreign-born men are more likely to marry than native-born men. But these factors do not have as significant an impact on women’s marriage behavior. In Europe, researchers have conducted studies examining male and female transitions to adulthood in twenty-four countries using survey data for the 1980s and 1990s. They find that educational attainment’s generally negative effect on fertility is stronger for women than for men. Also, unemployment leads to men’s postponement of marriage, whereas it affects women in two distinct ways. It either accelerates or slows down women’s timing of marriage. The effect of religion is stronger among women than men. Furthermore, being Catholic and attending church services affect men and women’s parenthood timing in different ways in predominantly Catholic countries. Other relevant factors such as parental influence have been shown to have a different impact for males compared to females (Corijn and Klijzing 2001).

Historically, women have been tied to motherhood, and this association is deeply rooted in law and policy, in the ways that jobs are structured, and the ways that family relations are navigated. Many of the studies of fertility and parenthood undertaken by demographers have been shaped by this historical association as well (Riley 2005). Together with the biological and methodological factors...
stated above, this has resulted in the decreased attention given to males in fertility research. Yet, as mentioned earlier, biological and demographic analyses have shown that fertility and parenting are not simply female issues—they are issues involving both men and women. The study of fertility should not only focus on females. Critical demography has promoted bringing men into population studies (Horton 1999; Coleman 2000) and Greenhalgh (1990) and others have argued that it is necessary to incorporate gender studies into studies of demography in order to gain a more balanced picture of demographic issues. Together with lowest-low fertility, unbalanced sex ratios at birth, and the demography of gay males and lesbians, male fertility and men’s influence on decisions about bearing and rearing children have become emerging issues of population study.

Fertility, Land

The fertility of soil refers to its ability to function in the growing of crop plants. Soil fertility is frequently defined narrowly as the ability of the soil to provide nutrients that are essential for plant growth and the soil having a pH in the range needed for the specific crops grown (most plants do well in the pH range of 6 to 7). If soils are very acidic, below pH 5.5, many crop plants are harmed by the lack of nutrients as well as the presence of soluble aluminum, which can be toxic to plants. On the other hand, some crops such as cassava do well in the acidic and low-nutrient soils of the tropics. Most of the eighteen essential elements for plants come from the soil. Of the nutrients supplied by the soil, nitrogen, phosphorus, and potassium are the ones needed in the largest amounts and are frequently applied in commercial fertilizers. Other nutrients, such as calcium, sulfur, and magnesium, are needed in lesser amounts while the micronutrients, such as iron, manganese, copper, and zinc, are needed in very small amounts and are not as commonly deficient.

A broader view of soil fertility has recently developed that is sometimes referred to as soil health or soil quality. In this more comprehensive view, equal consideration is given to the physical and biological properties of soil that are important to plants, along with the chemical properties. For example, a soil may have excellent nutrient availability but be too wet or compact for crops to grow properly or might have high populations of plant disease organisms or parasitic nematodes. The chemical fertility of the soil is usually determined by laboratory analysis of a composite sample taken from a field. The tests normally included in routine soil analysis are for pH, available nutrients such as phosphorus, potassium, calcium, and magnesium, and lime requirements. Other tests commonly done are salinity and percent saturation with sodium (both in arid regions) and amount of organic matter. In determining the broader health of the soil, the degree of compaction, and root health are usually evaluated in the field, and some laboratories determine waterholding capacity and indicators of biological activity.

Topsoil, usually the top six inches or more, is the most fertile part of the soil. It contains higher amounts of organic matter and nutrients, has more biological activity, retains water more easily, and is usually better aerated than subsoil. Plentiful organic matter is the key to healthy, fertile soils because it has profound and positive effects on almost all soil properties—chemical, biological, and physical. It helps soils store water, resist compaction, make nutrients more available to plants, maintain a thriving and diverse populations of organisms, and so on.

When forests or grasslands are converted to agricultural use, these virgin soils are usually productive for a number of years, even without addition of fertilizers or amendments. The soils usually have good physical, chemical, and biological properties. This is the basis for tropical slash-and-burn agriculture, a twenty- to forty-year cycle in which the trees in a forest plot are first felled and burned. For a few short years, the nutrients stored in the soils and the positive effect of the ash on soils allow reasonable crop productivity. Much of the fertility of these soils is associated with organic matter or elements in the ash that are leached readily into the soil. Thus, in the traditional slash-and-burn system where no fertilizers or organic amendments are applied, after two or three years these soils are allowed to revert to forest.

Degradation of Soil Fertility

Soil degradation is a worldwide phenomenon that has occurred in many places since the development of agriculture. Soils can be degraded in a number of ways, such as nutrient depletion, organic matter depletion, development of saline or sodic (excess sodium) soils, removal of topsoil by accelerated erosion, and compaction.

In ancient times, crop production decreased in parts of Mesopotamia (in the Tigris and Euphrates valleys), as salts accumulated from irrigation water were not washed out regularly. The hillside agriculture of Greece, Turkey, and the Middle East was first practiced without terraces. Removal of the original forests and repeated plowing and working of these soils left their exposed surfaces smooth or with aggregates that were easily broken under the impact of rainfall. Rainfall, not able to penetrate the soil at the rate it fell, caused runoff and soil erosion. As Homer put it in the Iliad, “Many a hillside do the torrents furrow deeply, and down to the dark sea they rush headlong from the mountains with a mighty roar, and the tilled fields of men are wasted” (cited in Hillel 1992, p. 103). The large area of denuded hillsides in the region, with large areas of exposed bedrock or boulders, testify to the magnitude of this problem, which many feel severely stressed these societies to the point of either decline or aggressive adventures to find extra sources of food in other countries.
On highly leached and geologically old landforms such as occur in much of Africa, the loss of soil's ability to provide adequate nutrition to crop plants can happen very rapidly—within two or three years following cutting down the trees and burning them. (In places where the cycle of crops to forest and back to crops is greatly reduced, soils are much decreased in their fertility.) On the other hand, on the deep fertile grassland soils that developed in humid temperate regions, it can take decades of cropping before added nutrients are needed to maintain plant growth. These soils, naturally high in organic matter and able to supply crops with large amounts of nitrogen for years, usually also have large supplies of other plant nutrients. In his classic book *Slavery and Capitalism* (1961), Eric Williams makes the case that in the southeastern United States and the Caribbean it was the institution of slavery that allowed the large-scale exploitation of the land for cash crops (cotton and sugarcane). If free laborers were brought for the purpose of working large estates, as was the case in Australia, they would have abandoned the estates and started their own small farms. These smaller farms, Williams argued, would have not have been so hard on the soil because they would have grown more varied crops and used crop rotation. While this argument makes sense, the soils of the Caribbean and southeastern United States are easily depleted of their nutrients and, when on sloping land, prone to erosion. Thus, small farms applying the practices of the time might also have led to soil degradation, but perhaps not as rapidly as under the institution of slavery.

Between the two extremes of highly leached tropical and subtropical soils and deep grassland soils of the temperate regions are many of the soils of Europe and the eastern United States. These are the regions where modern agriculture first developed and the more intensive nature of cropping required large quantities of external nutrients to maintain plant growth year after year. Modern agriculture developed in a symbiotic relationship with industrial capitalism, and through the break in nutrient cycling capitalism has added new dimensions to the issue of soil degradation. Part of the reason for the need for large quantities of external nutrients is that, with the development of cities and capitalist farmers who sold most or all of what they produced, large amounts of nutrients were being removed from farmland and transported to cities in the form of food products. As Karl Marx wrote in volume 1 of *Capital*:

Capitalist production … disturbs the metabolic interaction between man and the earth, i.e. it prevents the return to the soil of its constituent elements consumed by man in the form of food and clothing; hence it hinders the operation of the eternal natural condition for the fertility of the soil…. All progress in capitalist agriculture is a progress in the art, not only of robbing the worker, but of robbing the soil; all progress in increasing the fertility of the soil for a given time is a progress towards ruining the more long-lasting sources of that fertility…. Capitalist production, therefore, only develops the techniques and degree of combination of the social process of production by simultaneously undermining the original sources of all wealth—the soil and the worker (1867, pp. 637–638).

**USE OF AMENDMENTS TO ENHANCE SOIL FERTILITY**

Although various animal manures and green manures were used for thousands of years to enhance the fertility of soils (and still are), in the nineteenth century the application of modern science to agriculture resulted in the knowledge that depletion of a few nutrients—nitrogen, phosphorus, and potassium—were likely to be limiting plant growth on many soils that had been farmed for years. The depleted, “worn-out” soils of Europe and the eastern United States created a strong demand for external nutrient sources. Bones, a source of phosphorus, were imported into Europe, and farmers even raided the graves of the Napoleonic battlefields to obtain them. In the 1840s phosphate became the first industrially produced fertilizer. But industrial production of nitrogen fertilizer would not happen until the after World War I (1914–1918), when the Haber-Bosch process for fixing nitrogen would begin to make this essential element more available. (And it was not until after World War II [1939–1945], when the munitions plants turned to making ammonium nitrate fertilizers, that the low price of nitrogen fertilizer greatly stimulated its use.) In the mid-1800s, in the absence of a ready supply of synthetically produced nitrogen, the use of guano from Peru, high in both nitrogen and phosphorus, came under British control. This caused the United States, in competition with European countries, to search abroad for sources of nutrients to help maintain soil fertility, referred to by the phrase “guano imperialism.” During this period, from 1856 (after passage of the Guano Island Act) to the early 1900s, the United States seized close to 100 island sources of guano.

A second major change in the cycling of nutrients took place after World War II. In this period, low-cost nitrogen fertilizers allowed farmers to forgo planting legume forage crops that had been part of an integrated crop farming system that included complex rotations and raising animals as well as crops. Farmers, no longer needing legumes or animal manures to supply their grain crops with nitrogen, began to specialize in one or two crops such as wheat and corn (and later soybeans). Animals, especially poultry, beef cows, and hogs, started to be raised.
on large farms that frequently imported feeds, made from mainly corn and soybeans, from other regions. The growth of these large-scale industrial animal facilities was brought about by the location of meat-processing facilities by highly integrated corporations. Many farmers are now raising chickens and hogs under contract, with little control over the actual production process. This separation of a large number of animals from the land that grows their feed has resulted in the necessity for crop farmers to use large quantities of fertilizers (to make up for the nutrients exported in their crops), while at the same time nutrients accumulate on the animal farms and result in significant pollution of groundwater and surface waters.

ECOLOGICAL MANAGEMENT OF SOIL FERTILITY

Although commercial fertilizers still have their place in agriculture, the high cost of nitrogen fertilizer in terms of energy use (and, therefore, price) and the ecological harm caused by phosphate mining mean that in the future more emphasis needs to be placed on more efficient nutrient cycling, the reintegration of animals back into cropping systems, and the return to legumes and manures as major sources of nitrogen and other nutrients for nonleguminous crops. Most soils can be greatly improved by implementation of ecologically sound practices for building healthy soils. One of the best approaches to improving soil health is to use various means to build up soil organic matter levels—such as adding manures and composts or other local sources of organic materials, using cover crops routinely, rotating row crops with hay-type forages, and reducing tillage intensity.

FESTINGER, LEON

1919–1989

Leon Festinger was a prominent American social psychologist. His work in social psychology focused on the impact of the social environment on the formation and change of attitudes, on processes of social comparison by which individuals evaluate their attitudes and abilities, and on the manner in which cognitive inconsistencies cause changes in attitudes and behaviors. He is best known for his work A Theory of Cognitive Dissonance (1957), which inspired a great deal of creative research and caused the term cognitive dissonance to become a part of public discourse.

Festinger was born on May 8, 1919, in Brooklyn, New York, and died on February 11, 1989. In 1939 he earned a bachelor of science degree in psychology at the City College of New York, where he became attracted to the work of psychologist Kurt Lewin (1890–1947). Festinger went to the University of Iowa to work with Lewin, and earned his PhD there in 1942. In 1945 Festinger joined Lewin in the Research Center for Group Dynamics at the Massachusetts Institute of Technology. When Lewin died unexpectedly in 1947, Festinger became director of the center and focused his attention fully on social psychology.

Festinger’s main contributions to social psychology occurred over the next twenty years. There are three landmark publications, each of which inspired research by many investigators. The first was “Informal Social Communication,” published in Psychological Review in 1950. This article showed how pressures toward uniformity of opinion in small, informal groups could lead to attitude change within the group. The second article, “A Theory of Social Comparison Processes,” was published in Human Relations in 1954. In this publication, Festinger used a set of formal propositions to explain the antecedent conditions and the consequences of comparing one’s own attitudes and abilities to those of others. In so doing, he showed how the pressures to uniformity, hypothesized in the earlier article, arose from the process of social comparison.

In A Theory of Cognitive Dissonance, Festinger’s third landmark publication, he hypothesized that any two bits of knowledge held by an individual could have three relationships to one another: they could be irrelevant to one
another, consonant if one follows from the other, or dissonant if the obverse of one follows from the other. Festinger hypothesized that cognitive dissonance is an aversive state and that an individual would be motivated to reduce dissonance. Dissonance could be reduced by changing attitudes, altering perceptions and evaluations, or changing one's own behavior. Because the theory was stated in such simple, general terms, it could be applied to a wide variety of situations. Festinger and his students were creative in finding applications for the theory and in devising incisive experiments to test their predictions. A number of these experiments are reported in Festinger's second book on dissonance theory, Conflict, Decisions, and Dissonance (1964).

Festinger's work on dissonance theory was the target of a number of critiques in the early 1960s. Critics attacked the structure of the theory as being too broad and not clearly defining the conditions under which dissonance would occur, as well as the complex experimental protocols employed by dissonance theory researchers. Over the ensuing decade, research replicating and extending earlier findings, as well as conceptual clarifications, notably by Elliot Aronson, effectively rebutted these critiques. As dissonance theory gained scientific acceptance, the term cognitive dissonance came to be used by columnists and other commentators to describe the psychological discomfort that follows the arrival of unwanted or unexpected information or events. This lay use of the term became popular, even though the conditions necessary for the occurrence of the state defined in the theory may not have been met in the situation to which the term was applied.

Subsequently, Festinger's research interests became focused on different issues. From 1963 to 1979 he studied human visual perception, making unique contributions to the research literature. He then turned his attention to early human history, producing a book, The Human Legacy (1983), in which he analyzed human problem solving and adaptation.

Leon Festinger left a legacy of enduring theoretical formulations, a distinctive style of experimentation in social psychology, and a large number of former students who have forged their own distinguished careers in social psychology.

FETISHIZATION

SEE Mystification.

FEUDAL MODE OF PRODUCTION

The feudal mode of production appears in the theorization of successive socioeconomic formations provided by Karl Marx (1818–1883), where it precedes the capitalist mode of production. Marx developed the concept of the feudal mode of production, in particular, in the section on “Pre-capitalist Economic Formations” of the Grundrisse (1857–1858) and in chapter 47 of the first volume of Capital (1867). He was not, however, interested in providing an account of the main features of feudal society as much as he was in focusing on the distinctive characteristics of capitalism compared to previous modes of production. In analyzing the feudal mode of production and its decline, he also tried to pinpoint the main factors that historically explain the rise of capitalism. The original formulations provided by Marx, Friedrich Engels (1820–1895), and Vladimir I. Lenin (1870–1924) viewed the feudal mode of production as an essentially economic dynamic of subjugation and exploitation. Subsequently, three main problems have framed twentieth-century Marxist scholarly debates on the feudal mode of production: its relations with serfdom, its interactions with feudalism as a political and juridical concept, and the reasons for its collapse and the transition to capitalism.

THE FEUDAL MODE OF PRODUCTION IN THE ANALYSES OF MARX, ENGELS, AND LENIN

Marx's definition of the feudal mode of production rests largely on the concept of feudal rent, which characterizes both relations of production and ways to extract surplus from the direct producers. The feudal rent requires the existence of large agricultural productive units (manors, demesne) owned by a landlord who, through coercive means, is able to force peasants to pay a rent in the form of labor (corvée), produce, or monetary tributes. In exchange, peasants living in villages are allowed to possess small individual landholdings (strips, virgates) and to access forests and pastures as common land. Surplus extracted as feudal rent reveals a relation of personal subordination between the peasant and the landlord, which is confirmed by the fact that the landlord is the supreme political authority over the geographical unit (the fief) that contains the demesne, peasants’ plots, and common land.

At the same time, the landlord is also a vassal, a personal subordinate of a higher-level noble or of the sover-
Feudal Mode of Production

eign, who recognizes the landlord's feudal authority in exchange for military services. Traditional customs—a theme touched on in Engels's *Socialism: Utopian and Scientific* (1892)—play a decisive role in sustaining these webs of hierarchies, obligations, and subjection, which appear natural and immutable. Finally, for Marx and Engels, the feudal mode of production reflects a radical opposition between the countryside and the city, which remains economically marginal and undeveloped.

Engels's discussion of feudalism, especially in the *Origins of the Family, Private Property, and the State* (1884), balanced Marx's emphasis on economic causal relations with the significance of communal landownership as a source of peasant resistance to the landlord. Such themes also surfaced in debates on the feudal mode of production in revolutionary Russia. Nikolai Bukharin (1888–1938) and especially Lenin's *The Development of Capitalism in Russia* (1899) describe czarist Russia as a feudal society where the oppressed peasants constitute a serfdom that retains strong connections with communal forms of property. In Lenin, moreover, Russian feudalism is not a single mode of production but rather a "social formation" where other modes, including a rising capitalism, exist alongside feudal landholding under the authority of a strong, centralized absolutist state. As in other parts of eastern Europe, feudal landlords show for Lenin the tendency to evolve and become bourgeois agrarian Junkers who, in what Lenin calls the Prussian road, start hiring waged laborers to produce for the market.

**LATER MARXIST DEBATES AND THE TRANSITION FROM FEUDALISM TO CAPITALISM**

The issues raised by Lenin's discussion of feudalism—on the role of serfdom, political absolutism, and the modes of transition to capitalism—resonated in postwar Marxist debates. There, moreover, the geographical focus of the feudal mode of production was broadened beyond the European context as Marxist scholars identified feudal economic and political relations in the shogunate during the Tokugawa age in Japan (1600s to mid-1800s), in imperial Ethiopia (late 1800s to 1970s), and, more controversially, in prerevolutionary China.

A major object of debate concerned the relations between the feudal mode of production and feudalism intended as a broad political, juridical, and ideological construct. Non-Marxist historians (Marc Bloch, Otto Hintze, Robert Boutruche, Georges Duby) have advanced this latter perspective, which, however, also influences the thorough Marxist analysis proposed by Perry Anderson (1974). He sees the construction of the feudal mode of production in Europe, and its local specificities, not just as products of economic causality. They are also a reflection of different forms of “parcellization of sovereignty” and of shifting interactions between juridical concepts of private property in Roman law and village warrior aristocracy in the Germanic tradition. Conversely, he regards the rise of western European absolute monarchies in the 1500s and 1600s—when feudalism was also established in eastern Europe—as a sign of transformation in societies whose feudal economies are increasingly producing for international commodity markets.

Anderson's view markedly contrasts with that of Barry Hindess and Paul Hirst (1975), who argue that the political forms of feudalism are irrelevant to define the feudal mode of production, which was an economic formation based on a tax-rent surplus extraction that relied entirely on the aristocracy's control of the land. Consequently, for Hindess and Hirst, serfdom as a juridical condition is of secondary importance in conceptualizing the feudal mode of production. The concept, in fact, includes every rural society where landlords (not the state, as in the Asiatic mode of production) raise rent and taxes from peasants that are not waged laborers, as in capitalism, or slaves, as in antiquity.

Finally, from the 1950s to the 1970s, an important Marxist debate focused on the dynamics of the crisis of feudalism and its transition to capitalism. Economist Paul Sweezy (1910–2004) saw the feudal mode of production as an inefficient, unproductive, socioeconomic structure, which was ultimately destroyed by the growth of commodity markets and the rise of profit-oriented urban entrepreneurs. Robert Brenner opposed to this view an image of the feudal mode of production as a dynamic, differentiated, even market-oriented system, whose crisis is explained by changing forms of property and social relations. Therefore, in England, the state supported large landlords' “enclosures” and the expulsion of peasants in the context of the Industrial Revolution, while in France feudal landownership was undermined by the resilience of small independent peasant agriculture. Other Marxist historians, like Maurice Dobb (1900–1976) and Rodney Hilton (1916–2002), more directly emphasized the role of class struggles between landlords and peasants in explaining the crisis and collapse of the feudal mode of production.

**BIBLIOGRAPHY**

FEUDALISM

The term feudalism is used to describe a variety of social, economic, and political obligations and relationships that were prevalent in medieval Europe, especially from the eleventh through thirteenth centuries, though the feudal system existed before and well after that period in several cases. For instance, serfdom was not abolished officially in czarist Russia until 1861. Feudalism has also been used to describe ancient or former social and political systems in Japan, China, India, the Middle East, and North Africa. The term is controversial and has been said to be overapplied or misapplied by historians and social scientists.

Feudalism was never a single monolithic system practiced by all societies in Europe. There was a great deal of variation across societies in the practice and rites of the feudal order in nations such as France, the German states, England, Spain, and Russia. Although feudalism in Japan, India, China, and Africa had a few common elements, those systems differed significantly from the European varieties. Nonetheless, the term feudalism has been applied most regularly and commonly to many medieval European systems of social, economic, and political organization.

THE ORIGINS OF FEUDALISM

Feudalism emerged as a form of social, economic, and political organization after the fall of the Roman Empire between 300 and 500 CE and especially after the death of the Holy Roman emperor Charlemagne in 814. The origins of feudalism are numerous and debated but tend to be identified as an intermixture of Germanic and Roman law as well as Catholic doctrine. However, its origins were as practical as they were legal or philosophical. Repeated invasions and attacks from the north and east had made the lands of the former Roman and Holy Roman empires insecure. New patterns of governance and security were required to protect crops, animals, and persons.

The feudal system was one of hierarchy in which nobles, who were sovereign over the most valuable commodity of that time—land—ruled over peasants (serfs) who were tied permanently to the land. The system was social in that it distinguished between classes: nobility and peasantry; economic in that it divided the major means of production—land for agriculture—among the elite nobility; and political in that it created a hierarchical power structure than ran from kings and other high nobles down to middle and lower nobles and finally to peasants, who had limited or no social, economic, and political power.

THE FEUDAL CONSTITUTION

The feudal system was based on what later would be called a contract, or constitution, encompassing the obligations and allegiances that bound king to lord. The feudal contract consisted of homagium and investitures, in which a tenant offered his fealty and a commitment of support by paying homage to a lord and the lord would grant the tenant an investiture, or title over the land, for a specific tenure in return for payments. Thus, it was a mutual relationship: The lord extended his protective services to his new vassal and his lands, and the tenant agreed to pay dues of wealth, food, arms, and military service to the lord.

The lowest rung on the feudal ladder was occupied by the peasantry. Before the tenth and eleventh centuries, most farmers held tenancy of their own land through contracts with regional lords or nobles. However, as invasion and attack became more significant and the costs of security increased, lords began making higher demands of their tenants. This forced more tenants into direct servitude as serfs: peasants tied to the land and in service to the lord. These serfs owed duties and they paid rents in cash or kind to their lords. The system was an economic one in which land was the most valuable commodity.

THE RISE AND FALL OF FEUDALISM

The feudal system expanded and became the dominant form of social, economic, and political organization in Europe because of both its success in providing security and stability and its promotion by the Catholic Church. The feudal order received strong support in the church and among the clergy, who saw its social and political hierarchy as a desirable form of governance and its economic organization as one of potential profit. The sovereignty and legitimacy of kings and nobles were tied closely to the Catholic Church, which thus was able to prosper by supporting and expanding the feudal order in Europe. The ascendency of the church to great wealth and power coincided with the expansion of feudalism.

Feudalism began to decline in parts of western Europe by the fourteenth century as a result of pressure from a number of interrelated events. The Renaissance (starting in the late fourteenth century), the Reformation (beginning in 1517), and the Industrial Revolution (beginning in the mid-1700s) led to significant philosophical, social, economic, and political transformation across western Europe. The Reformation and the Thirty Years War led to the collapse of the Holy Roman Empire and the rise of nation-states. The rise of the bourgeoisie and the decline of the feudal nobility led to the end of feudalism.
Fiction

Years' War (1618–1648) challenged and upended the Catholic Church's monopoly of spiritual and political authority, and the Industrial Revolution made the feudal agricultural order an anachronism. City-states and other feudal arrangements no longer were capable of providing social, economic, and political order and security in a more individualist and industrialized western Europe. The emergence of the modern state system based on nationality and the conceptions of popular and state sovereignty replaced that of the feudal state. The French Revolution of 1789 often is cited as supplying the death blow to the remnants of the ancient feudal regime. Although feudalism all but disappeared from western Europe between the fourteenth and eighteenth centuries, it survived in eastern Europe and Russia, which were affected far less by the progressive influences of the Renaissance, the Reformation, and the Industrial Revolution.

Feudalism has remained a topic of debate and study in the social sciences. In his early works, Karl Marx (Marx and Engels 2006) argued that feudalism, as a mode of production, was a necessary condition of societies on their way to capitalism and eventually communism. Some elements of feudal thought can be found in modern Catholic political doctrine and the principles of Christian democracy in many European societies and political parties. In addition, the feudal order has had long-standing social implications for class division, hierarchy, and identity in many European societies to the present day.

Beyond Europe, feudalism has been widely used to describe systems of elite-peasant socioeconomic and political arrangements in China, India, Japan, and especially Latin America. In the latter, latifundia relationships between landlords and peasants established during Spanish colonization survived the independence of the Latin American states. While resembling the European model imported from Spain, the feudalism of Latin America was also characterized by racial divisions between the white Spanish elite and the Indian or mixed-race peasantry, as well as imported African slaves. This, as well as other differences, have led to these systems being described as “semi-feudal” or “proto-feudal.” In conclusion, while feudalism has primarily been used in the European context, there have been numerous comparable systems in Latin America, East Asia, South Asia, and elsewhere, where the concept of feudalism may be applicable.

FICTION

Fictions include a variety of things: face-saving untruths that no one believes; devices of convenience in law; and unreal postulates such as the supposed inner planet Vulcan. This entry will address a narrower field: discourse that aims to convey a narrative of events but which is not intended by its maker to be taken as true. Fiction in this sense may appear in any medium, sometimes in language and sometimes not, and in a variety of genres. Historically, the most important genres seem to have been epic poetry, the comic and tragic forms of drama, and the novel, which has shown a generally increasing but not uniform tendency to naturalism over time. These genres have been transmuted by the vast and accelerating body of fictions in filmic and televisual media since the beginning of the twentieth century. Yet it is worth noting that nothing is known of most of the history of fictional narrative, since fiction may well be as old as language, and no story older than 5,000 years has survived. It is certainly hard to believe that fiction was absent from human society 30,000 years ago, given the impressive cultural, imaginative, and symbolic achievements of that period, visible in cave paintings and carved objects. Fiction may indeed be ten times older than that.

It is important to see that this definition of fiction is consistent with fiction having any number of purposes over and above the mere telling of a story, including didactic purposes. The definition requires only that the author should not present the events of the narrative as real; he or she may well intend to convince an audience of the truth of a certain ethical or political viewpoint that the narrative serves to suggest.

The idea of fiction generates a number of philosophical problems. One takes the form of puzzlement about why people are interested in fictional stories, given that they generally understand that events have not happened and characters do not exist. The answer is probably that the attraction of fiction is testimony to human delight in
the exercise of imagination and the rich emotional responses that imagining certain events generates. This issue has recently been given an evolutionary formulation: Why, given the pressing need for true information about the world, should humans ever have developed an interest in misrepresentations, which do not tell them how to feed, clothe, or house themselves? Human mental evolution seems likely to have been driven partly by social forces, making it advantageous for people to be able to understand, cooperate with, and sometimes deceive one another. Fiction may have developed as a kind of training ground on which to exercise mind-reading powers: a social assault course where live ammunition is banned. However there is little empirical evidence to support this hypothesis. Alternatively a taste for fiction might be a useless by-product of mental capacities that evolved for other purposes.

A further puzzle, and one with important practical ramifications, concerns the relation of a fiction’s world to the world of reality. Viewers or readers generally assume that a fiction will be set within a framework of truth, and are sensitive to any indication that the author is exploiting or has misplaced the boundary between this factual background and the events and characters created. The power of socially critical fiction, such as that of English novelist Charles Dickens (1812–1870) depends on this. Readers of espionage fiction will complain about minor mistakes in the description of technology; more seriously, others respond to fictions such as British writer Salman Rushdie’s (b. 1947) *Satanic Verses* (1988) with violent protest. While such responses may be deployed, the general idea that that fiction has a capacity to generate and control powerful emotional response, which may then influence behavior and belief, is not implausible. And sensitivity in this area is also testimony to the finely tuned capacity of human beings to grasp an author’s unarticulated intentions: One realizes that, while the story itself is fiction, there lies behind it a possibly multilayered set of intentions to persuade and perhaps to manipulate.

The status of fictional characters, who are often spoken of in familiar and even intimate terms, is an interesting facet of the analysis of fictions. Theorists have occasionally argued that fictional characters such as Sherlock Holmes exist in some way that, mysteriously, differs from the manner of existence of normal people. A better interpretation is that while what people think and say gives the impression that they are actually referring to fictional people as real, they in fact understand these characters to be make-believe. However creators of fiction do create entities subtly different from fictional people, namely the roles filled by fictional characters. These roles may be thought of as sets of characteristics that someone would have to possess if he were, for example, Sherlock Holmes (when in fact no one is). One can accept such statements as “Dickens created some very memorable characters” as true, but understand the reference to characters really to be a reference to roles.

The definition proposed at the beginning of this entry might be regarded by some as intolerably restrictive: There is a tendency in early-twenty-first-century thinking, influenced by postmodern ideas, to identify representations of any kind with fiction, on the grounds that representations select, and so distort, reality. In defense of the approach here taken there is a very significant difference between a story that is, and that is honestly presented as being, *made up*, and one that purports, perhaps only partially and perhaps with significant elements of misrepresentation, to relate real events. Categories such as the documentary film certainly need a nuanced approach that recognizes they are not and cannot be mere reflections of the real, but it is not appropriate to lump them into a vastly inflated category of the fictional class.

**FIELDS’ INDEX OF ECONOMIC INEQUALITY**

The task of devising proper measures of income inequality is inherently controversial. Individuals have different notions about inequality and cannot always agree on an equity-based ranking of income distributions. Despite theoretical disagreement on proper measurement, applied work frequently adopts measures such as the Gini coefficient. In a series of papers, Gary Fields questioned the use
Fields was specifically interested in measuring how inequality responds to income growth in a two-sector (dual) economy where each individual earns either a “low” or “high” income. Economic growth in this context consists in individuals transitioning from the low-income sector to the high-income sector.

Fields (1993) introduced the concepts of “elitism of the rich” and “isolation of the poor.” “Elitism of the rich” captures the idea that when there are few rich people in an economy, these individuals enjoy an elite position that contributes to a high level of inequality in the economy. Conversely, when there are only a few poor individuals, then “isolation of the poor” contributes significantly to disparity.

Fields contended that for most individuals some combination of these two concepts is necessary to properly measure inequality. Consider a six-person dual economy starting at a point where five people are poor and one is rich and moving to a point where four are poor and two are rich. Fields would say that in this example, elitism of the rich has declined dramatically owing to the presence of a second rich individual. Isolation of the poor has increased in this case because the remaining poor are fewer in number. In this case Fields would argue that the drop in elitism overpowers the increase in isolation, thus reducing inequality. Continuing with this progression, one finds that economic growth generates a U-shaped inequality path on Fields’ measure, in sharp contrast to the Gini coefficient, which produces an inverted-U for the same scenario.

Fields’ controversial analysis has prompted a number of academic responses. Paolo Figini (1998) noted that Field’s measure fails the test for Lorenz consistency (i.e., it violates commonly accepted axioms) when one allows for intrasector income inequality. Fields restricted his analysis to the special case where income is identical for each member of the high-income and low-income sectors.

John Burger (2001) provided a response to Fields’ (1987) contention that there is no intuition behind the traditional inverted-U shape generated by the Gini coefficient. Using Fields’ example, Burger demonstrated that as a six-person dual economy moves from incomes of (1, 1, 1, 1, 1, 4) to (1, 1, 1, 1, 4, 4), the individual income shares change from (1/9, 1/9, 1/9, 1/9, 1/9, 4/9) to (1/12, 1/12, 1/12, 1/12, 1/3, 1/3). The result is a transfer of income share from the four poor and one rich person to the newly wealthy second rich individual. Burger argued that the reduction in income share of several poor individuals impacts inequality more than the reduction in income share of the one wealthy individual, thus resulting in increased income inequality. Continuing with this logic, one finds that growth of the high-income sector generates an inequality path with an inverted-U shape. Burger concludes that the Gini coefficient and the resulting inverted-U shape are consistent with intuition based on income shares.

**FILIBUSTER**

Filibustering is behavior intended to delay the legislative process for strategic gain. In modern politics, filibustering is most likely to occur in the U.S. Senate because senators may speak for as long as they wish. As a result, senators have made speeches lasting several hours in order to slow the progress of bills they oppose. The longest single speech in Senate history is Strom Thurmond’s speech against the Civil Rights Act of 1957. Thurmond spoke for twenty-four hours and eighteen minutes.

Filibustering is not limited to long speeches, however, nor does it occur only in the U.S. Senate. Legislators also filibuster by making procedural motions to force unnecessary votes. Another popular tactic, known as a “disappearing quorum,” occurs when legislators refuse to vote on a bill in the hope that less than a quorum (i.e., the minimum number of legislators who must participate for a legislature to make a decision) of legislators will participate in the vote. During the nineteenth century, members of the U.S. House filibustered often and enthusiastically, a tradition that was suppressed by drastic precedents and rule changes in the 1890s. In 2003 Democrats in the Texas legislature left the state to avoid participating in a vote on altering congressional district boundaries. Since the Texas
Constitution requires two-thirds of each chamber to constitute a quorum, the Texas Democrats were able to stall the redistricting plan for months. Finally, filibustering occurs in non-U.S. legislatures as well. For example, filibustering has occurred in Taiwan’s Legislative Yuan during the final days of legislative sessions.

The Senate adopted a “cloture” rule to limit filibustering in 1917. Initially, the rule required a two-thirds majority to limit debate, and if cloture was approved each senator was limited to one additional hour of speaking. After several modifications between 1949 and 1986, the current version of the cloture rule allows a three-fifths majority to limit debate to a total of thirty hours for most issues, with a two-thirds majority necessary for rules changes. Additionally, senators have adopted rules and passed laws exempting a number of key issues, such as trade agreements and key budget legislation, from filibustering.

Despite these limits, filibustering has become increasingly common in the Senate. In the early twentieth century, filibusters were rare and typically occurred at the end of a legislative session. In addition, they were generally directed at budgetary or economic legislation. From the 1930s to the 1960s, filibusters were often used against civil rights legislation, but otherwise they were rare. But since about 1970, filibusters have become commonplace in the Senate. This change coincided with a tactical shift in Senate filibustering. While senators had historically been forced to physically occupy the chamber floor during a filibuster—as depicted in the 1939 film Mr. Smith Goes to Washington—during the 1960s and 1970s filibustering became less overt. Instead, senators typically threaten to filibuster as a strategic ploy, without ever actively filibustering on the Senate floor. Rather than waste the time of the chamber, Senate leaders typically avoid overt filibusters by compromising over the content of legislation and the terms of debate.

More recently, senators have disputed whether it is appropriate to filibuster judicial appointments. During President George W. Bush’s first term, ten out of forty-four nominations for the federal appeals courts were blocked by Democratic senators. Senate Republicans responded by threatening to use the “constitutional” or “nuclear” option of revising Senate precedents to allow majority cloture on judicial nominations. This controversy was defused by a bipartisan agreement in May 2005 to only allow filibusters against judicial nominations in “extreme circumstances.” The seven Republicans and seven Democrats who negotiated this agreement, who tended to be moderates within their party, were known as the “Gang of 14.”

FILM INDUSTRY

Since the last years of the nineteenth century, filmmaking, distribution, and exhibition have been a major cultural activity around the world. The usual disciplines associated with the social sciences—including political science, geography, history, law, psychiatry, psychology, and sociology—have been used to study the influence of the film industry. But at its core, any film industry consists of economic institutions that seek to maximize profits. These corporations produce the first copy of a film, make copies in various forms for distribution, and then rent (as in theaters) or sell copies (as in home videos). There is a small film community independent of Hollywood in the United States, as well as large and small industries in nations around the world.

Yet, since the early 1920s Hollywood has dominated the world’s film industry. In 1915 Adolph Zukor combined his production company (Famous Players Lasky) with Paramount distribution, and after World War II he began to acquire a chain of theaters, mostly in major U.S. cities, some outside the United States. Adroit competitors quickly followed: Loew’s/MGM, Fox, Warner Bros., and the Radio-Keith-Orpheum (RKO). All owned production, worldwide distribution, and vast chains of theaters. The so-called Big Five permitted minor companies to survive, hoping the U.S. government would not sue them for antitrust violations, but in May 1948 the U.S. Supreme Court forced the production-distribution divisions to sell theater divisions.

From 1965 to 1975, led by agent-turned-mogul Lew Wasserman, the Hollywood industrial system reinvented itself as a series of media conglomerates. Today television production provides a steady base of revenues, and the cinema blockbuster—the first being Wasserman’s Jaws in 1975—can pay off in billions. Other media business divisions synergize—meaning they cross-promote films with other products—as with Disney’s theme parks. Although...
film revenues from cinema attendance plunged, Hollywood companies prospered by selling videos in the 1980s and DVDs since the late 1990s. By 2000, theatrical revenues in the United States had fallen to an average of only 15 percent of the profits of an average Hollywood film; the bulk came from revenues associated with watching films on TV (including VHS, DVD, via cable, satellite, and broadcast).

The Hollywood industry still dominates world film revenues while making fewer films than India or Hong Kong. The Hollywood firms of Disney, Fox, Paramount, Sony, Universal, and Warner Bros. represent an exceptional oligopoly; although these six corporations are competitors, they also cooperate on many things, including issuing ratings to inform viewers on the appropriateness of film content for children and keeping open international distribution by working closely with the U.S. Department of State. Indeed, the agency they have fashioned for cooperation—the Motion Picture Association of America—ranks as one of the top lobbyists in Washington, D.C.

By the late twentieth century, although still called a film industry, Hollywood knew it was in the television business. In the United States each of the major studios (except Sony) is allied with a major television network: Disney-ABC, News Corporation’s Fox TV network, Viacom’s [Paramount] CBS, Warner’s CW, and General Electric’s Universal-NBC. They thus make television stories and series for their networks on the same lots where they make feature films. Indeed, some films, called “made-for-TV films,” premiere on television.

The “Hollywood” film industry has spanned the globe since the 1920s. Only Paramount has a Hollywood address, and it and its rivals distribute their films over the entire world, so although India and Hong Kong produce more movies, more Hollywood films are seen in more places than is any typical film from Asia. Indeed, all developed nations have film industries of their own, but all are limited in their globalization.

In addition, although Hollywood is the center of in-studio production and the final creative steps in film production, feature films are regularly shot away from Hollywood, on location. All states in the United States and most nations around the world are willing to subsidize production in their territories. For example, many Hollywood movies are filmed in Canada, which has fought to draw film production north of the United States. More often than not, a film set in New York City is really shot in Toronto or Vancouver, where it is cheaper to make. And although films are typically finally cut in studios in and around Los Angeles, the final decisions about which films will be made, which will be distributed, and in what forms they will be seen are made inside offices located in and around New York City.

Hollywood is also the most unionized industry in the United States today, because with a six-member oligopoly, unions face a common foe. Their members—from directors to the men and women who push sets and equipment—all are represented by guilds, or unions. Regularly, Hollywood’s six members sign a basic agreement with each union, and occasionally a guild will go on strike. This most often happens with the Writer’s Guild of America. These Hollywood-based unions are growing, bucking a trend of falling union membership in the United States.

Hollywood certainly has the most far reaching and profitable film industry in the world, but two other centers need to be singled out. India’s film industry is mostly concentrated in Mumbai (formerly Bombay), and is commonly referred to as “Bollywood,” an amalgamation of Bombay and Hollywood. The Indian film industry is multi-lingual and the largest in the world, producing more than 1,000 films per year as compared to Hollywood’s 200. The industry is supported mainly by a vast film-going Indian public (the largest in the world in terms of annual ticket sales), and Indian films have been gaining increasing popularity in the rest of the world—particularly in countries with large numbers of expatriate Indians.

Hong Kong is a filmmaking hub for the Chinese-speaking world (including the worldwide diaspora) and East Asia in general. For decades it was the third-largest motion picture industry in the world (after India and Hollywood) and the second-largest exporter (after Hollywood), principally with kung-fu action films dubbed into English and other languages. Despite an industry crisis starting in the mid-1990s, and Hong Kong’s return to Chinese sovereignty in July 1997, Hong Kong film has retained much of its distinctive identity and continues to play a prominent part on the world cinema stage. Unlike many other film industries, Hong Kong has enjoyed little to no direct government support, through either subsidies or import quotas. It has always been a thoroughly commercial cinema, concentrating on crowd-pleasing genres such as comedy and action, and heavily reliant on formulas, sequels, and remakes. As is typical of commercial cinemas, its heart is a highly developed star system, which in this case also features substantial overlap with the pop music industry.

The dominance of the industries in Hollywood, Bollywood, and Hong Kong has made it hard for the film industry to include independent filmmaking and documentaries. Yet these genres—truly independent filmmaking and filmed documentaries—turned to video in the late twentieth century; they were not shot on film, but on Beta video, then were premiered on TV networks, both privately owned and state-owned. Indeed, in most small nations of the world the few films made are subsidized by the government, and more and more often shot on video.
to lower costs. This is where the TV industry meets the film industry.

The much-anticipated coming of high-definition television (HDTV) at the beginning of the twenty-first century seemed to signal the end of the film industry. Yet, as HDTV standards develop, so does the quality of film. Thus, film remains easily the highest resolution of all "movie making." HDTV may "look like film," but engineers agree that the film image offers more information than any as yet developed or standardized high-definition image. As the twenty-first century began, if one wanted to see the highest definition, one still should attend a well-run cinema.

FINANCE
Finance refers to the study of the management of the assets of firms and households over time, given the calculated risks and expected returns. Also known as financial economics, it is one of the more recent fields in economics, with most of the key papers published after the middle of the twentieth century. The field of finance primarily includes: portfolio theory, which deals with how to achieve the maximum investment return for a given level of risk by diversifying between a risk-free asset and a portfolio of risky assets; asset pricing, which deals with the pricing of risky assets; and corporate finance, which explains corporate financial and investment decisions.

Modern finance started with the publication in 1952 of an article by Harry Markowitz (a 1990 Nobel laureate in economics) on portfolio selection. Markowitz introduced the notion of the mean-variance efficient portfolio, defined as the portfolio that provides either minimum variance for a given expected return, or maximum expected return for a given variance. Assuming a risk-averse investor, Markowitz proved that any other portfolio would not be optimal.

The next key contribution came more than a decade later in the area of asset pricing by William Sharpe (1964), John Lintner (1965), and Jan Mossin (1966) with the capital asset pricing model (CAPM). The model provides an equilibrium relationship between the risk of an asset and its expected return above the return of the risk-free asset. According to this relationship, the expected return of a risky asset in excess of the return of a risk-free asset, the so-called risk premium, is proportional to the risk premium of a portfolio holding the whole market and the extent to which the risky asset and the market move together, which is called the beta coefficient. The model implies that any other specific risk (nonmarket risk) can be diversified away and therefore does not justify any risk premium. A decade later, Stephen Ross’s (1976) arbitrage pricing theory (APT) proved that a similar relationship holds when one assumes no arbitrage opportunities (an arbitrage opportunity exists when a zero investment portfolio can yield a positive profit with certainty). The APT is less restrictive than the CAPM, since it only needs a few investors taking advantage of any existing arbitrage opportunities, eventually eliminating mispriced securities, while the CAPM assumes that all investors are mean-variance optimizers. Furthermore, the APT extends the CAPM by including other factors in addition to the market (multifactor models), such as macroeconomic variables.

Modern corporate finance theory, which studies a firm’s financing decisions and its evaluation of investment projects based on expected returns, has been primarily built on two theorems: the Modigliani-Miller theorem of capital structure (1958) and the Modigliani-Miller dividend policy theorem (1961), which are also known as the MM theorems. The first theorem states that the financing decision of a firm between debt and equity does not affect its value, while the second states that the dividend policy of a firm also does affect its value. The MM theorems gave their two authors the Nobel Prize in Economics (in 1985 for Franco Modigliani and in 1990 for Merton Miller) and led to a huge literature to explain why the theorems...
The practice of corporate finance is much broader. A typical corporate finance department in an investment bank deals primarily with initial public offerings (IPOs) and other underwriting services, as well as mergers and acquisitions.

The main financial assets include stocks (also called equity or shares) and fixed-income securities (also called bonds). Stocks are securities issued by private-owned firms to raise capital and are traded in the capital (or stock) markets (or exchanges). The investor’s return is determined by the dividend paid by the issuing firm and the change in the stock price (capital gain or loss). The equity holders of the company are its residual claimants, meaning that in the case that the company goes bankrupt, their compensation equals whatever is left (if anything) after all debt holders have been paid. Fixed-income securities are issued either by private or state-owned firms or by governments (central and local) to raise debt and are claims on a stream of income over a predetermined period. Their interest rate (also called the coupon rate) determines the stream of income during the life of the bond, in addition to the payment of the face value at maturity. Although the investor’s return is certain if the bond is held to maturity, and assuming the company does not go bankrupt, the return is uncertain if the investor decides to sell the bond before maturity, since the price of the bond fluctuates as the bond is traded in the market.

Since the mid-1970s, the study of more “exotic” financial instruments has gained popularity, and the trading of derivative securities has spread widely in the capital markets. Derivative securities (or contingent claims, or simply derivatives) are securities whose value depends on other securities. They include options, forward contracts, futures, swaps, and many other securities that give the right to its holder to buy, sell, or exchange the underlined security or securities under prespecified conditions. A call (put) option provides the option to its holder to buy (sell) a security by a prespecified date, at a prespecified price, called the exercise or strike price—the call (put) option will be exercised only if the market price is higher (lower) than the exercise price. A forward contract is an agreement to buy or sell a security at a prespecified date, at a prespecified price. A future contract is a forward contract that is traded in the market. In contrast to options, forward and future contracts are always exercised. Swaps are agreements to exchange cash flows during a prespecified period and based on a predetermined formula. The popularity of derivative securities increased rapidly in the years that followed the publication of the Black and Scholes option pricing formula (Black and Scholes 1973; Merton 1973), which gave Myron Scholes and Robert Merton the 1997 Nobel Prize in Economics—Fischer Black died two years before the award. The beauty of the formula is that it includes only known variables, as it depends on the volatility of the price of the underlined stock rather than its expected return.

The main function of derivative securities is risk insurance (hedging), although derivatives are also used for speculation. To use some examples, a put option insures a stockholder from a fall in the stock price below the exercise price, a forward contract provides a fixed payment to a farmer for his or her future production regardless of weather conditions, and a swap agreement allows a firm to exchange a floating stream of revenue with a fixed stream in order to pay its fixed obligations. On the other hand, derivatives allow speculators to take large bets with relatively small initial capital, since instead of paying for the whole price of the underlined security they only have to pay the much lower price of the derivative. Speculators can take very large exposures using derivatives that can lead to huge gains or losses. Recent examples of such speculation going bad include the collapse of Britain’s Barings Bank in 1995 from speculation from a single trader in its Singapore office, and the collapse of the U.S. hedge fund Long-Term Capital Management, which after an annual return of more than 40 percent in the 1994–1997 period, lost $4.6 billion in just four months in 1998 and had to be rescued by a package from leading U.S. investment and commercial banks orchestrated by the Federal Reserve (ironically, Scholes and Merton were on the board of the fund).

The trading of the financial instruments takes place in financial markets, while the financial transactions are performed by financial institutions and investors. The financial markets include the money market (trading of very short-term debt securities), the bond market, the stock market, and various derivative markets. A stock is first sold in a stock market through an IPO and is then traded in secondary markets. Some stocks are traded in informal exchanges, called over-the-counter markets (or OTC). The financial institutions can be separated into banks and nonbanks, although this distinction is not always clear and today’s large and often multinational, or even global, financial conglomerates offer the whole range of financial services. The first includes primarily commercial banks, savings institutions, and credit unions, while the second includes investment banks, insurance companies, leasing companies, and investment funds.

Finance is linked with other fields in economics and is increasingly relevant for economic policy. Macroeconomists study finance to understand how capital markets affect the impact of economic policies on the economy. Effective monetary policy requires the knowledge of its potential impact on capital markets but also on the way capital markets allow the transmission of monetary policy itself. International economics includes the study of international finance (also called open-economy...
Finance, Public

macroeconomics), which studies, among other issues, the interaction of international capital markets and the movement of capital across borders. The field of finance also uses concepts and tools from other fields to extend its understanding of capital markets and investment decisions. It uses microeconomic theory to explain the decisions of rational investors based on utility maximization, econometrics to study the behavior (trends and patterns) of financial variables, and mathematics to model the behavior of financial markets and of investors and to price financial assets.

It should be emphasized that finance is not what most noneconomists believe it is, which is the study of “how to make money.” In such a case, all financial economists, quite smart people indeed, would have been rich. If anything, the field argues that markets are efficient and that one cannot consistently outperform the market—those who sometimes do are just lucky. There is a huge literature attempting to find evidence against the so-called efficient market hypothesis (EMH). Although some studies have discovered some patterns against the hypothesis, either there is no money to make or once transaction costs are taken into account or the patterns disappear soon after being discovered as investors take advantage of them. The EMH suggests that in order to outperform the market one would need to have superior information from the other investors, which is impossible, except in the case of inside information. However, trading based on inside information, although not rare, is illegal in most countries.

The ongoing globalization process and the tremendous advances in information technology in recent decades are having a profound impact on the field of finance. Investors diversify by choosing from investment opportunities provided by a global market, firms can issue stocks at stock markets abroad, governments can sell their bonds to foreign investors, and speculators can bet against more or less any foreign currency they choose. The large size of international capital movements allows emerging markets to finance their development using foreign capital. However, when the investors’ appetite for risk changes, either because of bad economic policies in the recipient countries or due to negative spillover effects from policies or shocks in other countries, the result can be a serious economic slowdown, or even a banking and a broader financial crisis, as shown by the crises in Mexico (1994), East Asia (1997–1998), Russia (1998), and Argentina (2001).

Optimists argue that the best is yet to come in the field of finance. Their belief is based on the argument that the use of advanced financial instruments and information technology has just started. Robert Shiller (2003) proposes a new financial order in which it will be possible to insure against more or less any nonfinancial risk. Individuals will be able to insure against their uncertain income from the profession of their choice or against unexpected negative shocks to their economic well-being, countries will be able to sell debt with a repayment plan that depends on their economic growth, and different generations will be able to share the cost of social security. According to pure financial theory, one should be able to sell any kind of risk to someone willing to buy it for the right price and diversify it away. Indeed, this is increasingly seen in today’s global financial markets.

FINANCE, PUBLIC

Public finance is the study of the economic activities of governments. These activities are expressed mostly through budgets, so it is the taxes and expenditures that comprise those budgets that are the primary objects of fis-
cal theorizing. It should also be noted, however, that nearly anything that can be accomplished through a budget can also be accomplished through regulation. For instance, a government could simply require parents to send their children to approved schools; this would bypass the budget without eliminating government-directed schooling. Recognition that regulations can substitute for budgets calls into question the common use of budgetary magnitudes to measure the size of government within an economy.

TWO APPROACHES TO PUBLIC FINANCE

The history of fiscal scholarship reveals two distinct approaches to public finance, as set forth in chapter 1 of Richard Wagner's *Fiscal Sociology and the Theory of Public Finance* (2007). These contrasting approaches can be described as "systems design" and "social theorizing." In the second half of the twentieth century the most prominent expositors of these distinct approaches were Richard Musgrave and James Buchanan. Musgrave's *Theory of Public Finance* (1959) represents the modern-classic statement of public finance as an exercise in systems design. Buchanan's *Public Finance in Democratic Process* (1967) presents public finance as an element of social theorizing, and it set forth an orientation that subsequently blossomed into the field of study now known as public choice.

Systems design and social theorizing represent distinct orientations toward their subject matter. These orientations are not incompatible, but they do pose different analytical questions. The systems design orientation treats public finance as a practical discipline in the service of statecraft: The purpose of public finance is to supply guidance for the conduct of statecraft. Following Musgrave (1959), governments would act to correct market failures by providing public goods that would otherwise not be supplied through ordinary market transactions.

In contrast, public finance approached as an element of social theorizing seeks to provide understanding about the actual conduct of government within society. Following Buchanan (1967), governments are arenas of human interaction and are populated by the same types of people with the same types of interests and concerns as populate other arenas in society. If we start from the universal principle that people seek to replace circumstances they value less highly with circumstances they value more highly, public finance as social theorizing seeks to explore how this principle plays out within governments. Governments and markets are both treated as complex processes of human interaction, and the primary analytical challenge for this approach to public finance is to develop better understanding of the actual conduct of statecraft, as distinct from seeking to participate in statecraft.

ILLUSTRATING THE TWO APPROACHES

The systems design approach to public finance dichotomizes the world of goods into private goods and public goods, and assigns public goods to the domain of public finance. The central analytical question revolves around efficiency in the allocation of resources between public and private goods. It is commonly presumed that market arrangements operate well to organize the supply of private goods, but not of public goods. State action is thus conceptualized as providing what market-based organization cannot provide.

In contrast, the social theory orientation starts from recognition that the theoretical distinction between public and private goods does not provide a good frame of reference for understanding the world of practice. A person cannot take the theoretical distinction between public and private goods and apply it directly to the world of experience: Many public goods are provided through markets and governments provide many private goods. For instance, governments provide security services, but security is also organized through markets; educational services and recreational services are provided by governments as well as through markets; governments sometimes regulate product quality, but market arrangements likewise regulate product quality. This will be the same nearly everywhere one wanders throughout the world of goods.

For the social theory approach to public finance, the analytical focal point is the organization of human activity, not some notion of optimal resource allocation. After all, resources cannot allocate themselves. Only people can do this, and they do so within various societal configurations. The social theory approach seeks to locate fiscal activity as occurring on the same plane as market activity: Both types of activity reflect the same underlying economic principles of preference and cost, and fiscal theorizing seeks to explore how those simple principles generate complex patterns of societal organization through interactions among the members of society.

Vincent Ostrom’s *The Intellectual Crisis in American Public Administration* (1973) is a splendid and seminal treatment of the distinction between the two approaches. Public finance has a presence throughout the world of goods, but in no case do state and market represent distinct domains of human activity. The domains are tightly intertwined, and in both complementary and competitive manners. If we ask whether water, airports, or anything else are better supplied by governments or through market-based commerce, we are asking a question that has little to do with understanding how societal processes actually operate.

Governments are typically involved at numerous places in the provision of water, airports, and numerous
Financial Instability Hypothesis

The American economist Hyman P. Minsky (1919–1996) set the realist criteria that, for a macroeconomic theory to be taken seriously, it had to make a depression “one of the possible states in which our type of capitalist economy can find itself” (1982, p. 5), and also explain why no such event had happened since the 1930s. Neoclassical theories failed that test, and Minsky devised the financial instability hypothesis (FIH) as an alternative. The hypothesis was based on an interpretation of chapter 12 of John Maynard Keynes’s (1883–1946) General Theory of Employment, Interest, and Money (1936).

The FIH sees finance as both essential to the market economy and the source of debt-financed boom-bust cycles. This cyclical process has a secular consequence, as money borrowed during booms generates repayment obligations that have to be fulfilled during slumps. As a result, debt levels ratchet up over a sequence of cycles, culminating in a debt-deflation. This regularity of the nineteenth century has not occurred since the Great Depression of the 1930s because of the development of “big government” and Federal Reserve intervention.

Unlike most economic models, the FIH is grounded in historical time, with an uncertain future. It commences with the economy having just stabilized after a previous debt-induced crisis, and with investors and lenders that are consequently conservative in project valuation. As a result, given the stable economic conditions, most projects succeed. This surprises investors and financiers alike, leading both to revise their expectations upward. Stable economic times thus cause rising expectations—“stability is destabilizing,” in one of Minsky’s most apt aphorisms—and these expectations are shared. Information asymmetry, a popular neoclassical explanation for credit problems, is of little importance.

Rising expectations increase investment, the finance for which is forthcoming from equally optimistic banks, so that growing investment and endogenously expanding credit push the economy into a boom. Asset prices rise, causing them to diverge significantly from commodity prices. Expectations eventually become euphoric, setting the scene for the boom to unravel as the shift in expectations changes the economy’s investment profile.

A hedge climate, where investments are expected to meet all repayment obligations out of cash flow, gives way to a speculative one, where principal must be rolled over. Ultimately, Ponzi finance becomes prominent: investments that can only succeed if the assets can be sold on a rising market.

The economy’s fragility thus rises, and even a small knock can bring it down. Expectations collapse, investment ceases, endogenous credit creation ends, and the economy enters a slump. What happens next depends on the institutional structure of the economy. In a pure market economy with a high debt to output level or commodity price deflation, the economy will enter a depression. In a modern mixed economy, cash flow from countercyclical government spending enables firms to repay debts during a slump, while Reserve Bank lender-of-last-resort actions prevent runs on financial institutions. The cycle continues, and a prolonged slump is avoided.

Minsky’s theory so suits the U.S. economic record that it sounds like a description, rather than a theory.
Financial Markets

However, a theory it is, amenable to mathematical expression in differential equation models, and consonant with empirical findings on the U.S. trade cycle.

FINANCIAL MARKETS

Financial markets are markets where financial transactions are conducted. Financial transactions generally refer to creation or transfer of financial assets, also known as financial instruments or securities. Financial transactions channel funds from investors who have an excess of available funds to issuers or borrowers who must borrow funds to finance their spending.

Since the early 1970s, financial markets in various countries have experienced significant development. As a result, world financial markets are larger, are highly integrated, and have a wide range of financial instruments available for investing and financing.

THE STRUCTURE OF FINANCIAL MARKETS

Financial markets comprise five key components: the debt market, the equity market, the foreign-exchange market, the mortgage market, and the derivative market. From the 1980s, each component market has been expanding in size, and an extensive array of new financial instruments have been initiated, especially in the mortgage market and the derivative market.

Debt instruments are traded in the debt market, also often referred to as the bond market. The debt market is important to economic activities because it provides an important channel for corporations and governments to finance their operations. Interactions between investors and borrowers in the bond market determine interest rates. The size of the world bond market was estimated at around $37 trillion at the start of 2002 (all currency figures are in U.S. dollars). Bonds denominated in dollars currently represent roughly half the value of all outstanding bonds in the world.

Equity instruments are traded in the equity market, also known as the stock market. The stock market is the most widely followed financial market in the United States. It is important because fluctuations in stock prices affect investors’ wealth and hence their saving and consumption behavior, as well as the amount of funds that can be raised by selling newly issued stocks to finance investment spending. The size of world developed equity markets expanded from $892 billion in 1974 to $25,276 billion at the end of 2001, with the U.S. market accounting for 57 percent of the world developed equity market in 2001.

Foreign-exchange markets are where currencies are converted so that funds can be moved from one country to another. Activities in the foreign-exchange market determine the foreign-exchange rate, the price of one currency in terms of another. The volume of foreign-exchange transactions worldwide averages over $1 trillion daily.

A mortgage is a long-term loan secured by a pledge of real estate. Mortgage-backed securities (also called securitized mortgages) are securities issued to sell mortgages directly to investors. The securities are secured by a large number of mortgages packaged into a mortgage pool. The most common type of mortgage-backed security is a mortgage pass-through, a security that promises to distribute to investors the cash flows from mortgage payments made by borrowers in the underlying mortgage pool. A 1980s innovation in the mortgage-backed security market has been the collateralized-mortgage obligation (CMO), a security created by redistributing the cash flows of the underlying mortgage pool into different bond classes. Mortgage-backed securities have been a very important development in financial markets in the 1980s and 1990s. The value of mortgage principal held in mortgage pools increased from $350 billion in 1984 to nearly $2,500 billion in 1999.

Financial derivatives are contracts that derive their values from the underlying financial assets. Derivative instruments include options contracts, futures contracts, forward contracts, swap agreements, and cap and floor agreements. These instruments allow market players to achieve financial goals and manage financial risks more efficiently. Since the introduction of financial derivatives in the 1970s, markets for them have been developing rapidly. In 2001 global exchange-traded futures and options contract volume reached 4.28 billion contracts, and the top three types of contracts—equity indices, interest rates,
and individual equities—are all financial derivatives. Together they accounted for 88.7 percent of total contract volume.

CLASSIFICATION OF FINANCIAL MARKETS

Financial markets can be categorized in different several ways, revealing features of various market segments. One popular way to classify financial markets is by the maturity of the financial assets traded. The money market is a financial market in which only short-term debt instruments (original maturity of less than one year) are traded. The capital market is a market in which longer-term debt (original maturity of one year or greater) and equity instruments are traded. In general, money-market securities are more widely traded and tend to be more liquid.

Another way to classify financial markets is by whether the financial instruments are newly issued. A primary market is a financial market in which a borrower issues new securities in exchange for cash from investors. Once securities are sold by the original purchasers, they may be traded in the secondary market. Secondary markets can be organized in two ways. One is as an organized exchange, which brings buyers and sellers of securities together (via their representatives) in one central location to conduct trades. The other is as an over-the-counter (OTC) market, in which over-the-counter dealers located at different sites but connected with each other through computer networks undertake transactions to buy and sell securities “over the counter.” Many common stocks are traded over the counter, although shares of the largest corporations are traded at organized stock exchanges, such as the New York Stock Exchange.

THE ROLE OF FINANCIAL MARKETS

By channeling funds from investors to issuers and borrowers, financial markets enhance production and allocation efficiencies in the overall economy. Financial markets also perform the important function of price discovery. The activities of buyers and sellers in a financial market determine the prices of the traded assets, which provide guidance on how funds in the economy should be allocated among financial assets.

Additionally, financial markets provide a mechanism for managing risks. Various financial assets traded in financial markets provide different payment patterns, and this redistributes and reallocates the risk associated with the future cash flows among issuers and investors.

Financial markets also offer liquidity by providing a mechanism for investors to sell or purchase financial assets. The presence of organized financial markets reduces the search and information costs of transactions, such as the money spent to advertise the desire to sell or purchase a financial asset. In an efficient market, the market price reflects the aggregate input of all market participants (Fabozzi and Modigliani 2003).

THE INTERNATIONALIZATION OF FINANCIAL MARKETS

The internationalization of financial markets has become an important trend. The significant growth of foreign financial markets has been driven mainly by deregulation of markets in financial centers worldwide and technological advances enabling more efficient communication, as well as market monitoring and analysis.

The internationalization of financial markets has also been prompted by numerous studies on the benefits of diversification that includes international stocks. Specifically, including securities from different countries in a portfolio may lower the portfolio’s risk without reducing its expected return. The benefits of diversification arise from the fact that asset prices across international financial markets are not highly correlated.

The nature and extent of the internationalization of financial markets are well reflected by developments in international bond markets and world stock markets. Eurobonds are long-term debt securities sold outside the borrower’s country to raise long-term capital in a currency other than that of the country where they are sold. Eurobonds are relatively new instruments in the international bond market, yet the volume of new issues of Eurobonds grew nearly four times from $167 billion in 1990 to $642 billion in 2001, and the market capitalization of Eurobonds stood at $7 trillion at the start of 2002. As for stock markets, while the U.S. stock market remains the largest in the world, foreign stock markets are becoming increasingly important. Japan and the United Kingdom have the largest markets outside of the United States. As of the end of 2001, the size of Japanese market was $2,528 billion, and that of British market was $2,275 billion. Stock markets in many developing economies, also known as emerging markets, picked up their pace of development in the 1980s. In 2001 the combined market value of emerging markets was around $2,400 billion, accounting for 8.7 percent of total world market capitalization that year.

Because financial markets are internationalized, issuers and investors in any country need not be limited to their domestic financial markets. The internationalization of financial markets is having a profound effect by leading the way to a more integrated world economy in which flows of goods and technology between countries are more commonplace (Mishkin and Eakins 2000).
FIRM

In 1937, Ronald Coase, who would win a Nobel Prize in 1991, wrote a seminal paper titled “The Nature of the Firm.” This paper is now traditionally considered to be the origin of the development of an economic theory of the firm. Coase argued that the firm was more than the purely technical vision of incorporating inputs and generating outputs, that it had a concrete existence in the business world, and that its internal modes of organization (especially the coordination of individuals by hierarchies) were different from simple market transactions (which are coordinated by prices). He encouraged economists to elaborate realistic hypotheses on what a firm is and what a firm does.

Today, the research agenda opened up by Coase (1937) is far from complete. More recent works on the economics of the firm show how difficult it is to fully grasp and qualify this subject. Thus, the economics of the firm is a combination of different subjects, and no single model or theory captures all elements of the puzzle.

MANAGERIAL FIRMS

The focus of economists on large managerial firms reflects the impact that this type of firm played in the early stages of the capitalist economist system (1900–1970s), when large, vertically integrated corporations were the dominant form of organization. Joseph Schumpeter (1942) qualified them as the major engines of production, while Alfred Chandler (1977) described the emergence of a “visible hand” era driven by these firms. These organizations represent an important field of investigation because they have significant power in the market, they are able to affect the social and economic environment, and they can elaborate complex strategies based on an appropriate organizational structure. Further, these firms have two distinctive features: (1) There is a separation between ownership and control, so the professional manager is able to define the objectives of the firm, and (2) There is a united, rather than a multidivisional, form of internal organization. These characteristics became one of the privileged fields of exploration of agency theory and the transaction costs approach, which were interpreted in terms of private information and opportunism. In the first case, the manager benefits from private information that the investor cannot access, leaving room for opportunistic behaviors. In the second case, the united organization of the firm favors the development of suboptimal levels of effort that only become observable when competition is introduced among the different divisions of the firm.

There is surprisingly little agreement on what the objectives of the firm are. William Baumol (1959), for example, supports the maximization of sales or the growth rate of sales as the main objective. Oliver Williamson (1964), however, advocates the maximization of the managers’ discretionary power through opportunistic behaviors. Herbert Simon (1947) has criticized both alternatives, arguing that firms that have only a “limited rationality” due to the uncertainty of the environment will only pursue limited objectives, a process he calls “satisficing.” In this perspective, the search for profit will not be made on the basis of achieving maximum profit. In fact, it is impossible to estimate maximum profit because knowledge is not perfect. The objective can only be to maintain a satisfying profit level in order to keep the firm afloat in an uncertain world.

ENTREPRENEURIAL FIRMS

The discovery that the capitalist system underwent a second period of transition during the latter half of the twentieth century, especially from the late 1970s (a period Richard Langlois [2003] labeled the “vanishing hand” era), marks the beginning of a specific focus by economists on a novel sort of firm. Small, vertically disintegrated firms have generally performed as well as large firms. This view is supported by the remarkable persistence of the skewed size distribution of firms in industrial dynamics (i.e., a large number of small firms and a small number of large firms), and by the extremely important contribution of small firms to global economic development (Geroski 1995; Audretsch 1995). In the late 1990s, the critical resource theory was developed by Rajuram Rajan and Luigi Zingales (1998) to explain the performance of knowledge-intensive companies in which an entrepreneur plays a central role in knowledge creation. The point of departure of the analysis is that the nature of

Donald Lien
Mei Zhang
the firm has effectively been changing. In the modern firm, the entrepreneur has a critical resource due to specific skills, talents, and ideas, which are the most important source of potential value creation for the firm. The effective value created by the firm is ultimately dependent on how the entrepreneur develops complementarities between his or her own specific resource and the resources of collaborators.

**DECISION MAKING, OWNERSHIP, AND POWER**

One of the important issues in the economics of the firm is related to who has the power to make decisions. The concept of ownership has traditionally been perceived as the ownership of physical assets and power and authority have traditionally been based on this vision of ownership. Today, however, firms are also composed of a range of other resources, such as creative knowledge, ideas, and unique skills; professional control; and corporate reputation, which sometimes generate a higher value than physical assets.

Within small firms the founder/entrepreneur generally has the decision-making power, while in large firms the CEO and the board of directors make the major decisions. In small firms, however, the founder, who often has a technical skill, is often replaced, or at least assisted, by a professional manager or a venture capitalist, whose task is to transform this technical knowledge into a commercial opportunity. In large firms, the board of directors can be composed of shareholders, who may significantly influence the decision-making process.

These observations have stimulated a large number of analytical and empirical investigations. First, the respective tasks and scopes of experience of the entrepreneur, the manager, and the venture capitalist within small firms engendered a specific field of research. Different arrangements among the entrepreneur, the manager, and the venture capitalist can be envisaged, including a sharing of power where each contributes in a complementary manner to the development of the company, or exclusive power held by the fund provider in less risky businesses, where the entrepreneur or manager may have less incentive in terms of investment and effort (Blair 1995; Becht et al. 2005).

Second, the question of how large corporations should be owned and managed has been a recurrent theme. The emergence of the shareholder-value ideology has meant that corporate governance is often oriented toward the interests of investors. Uniformity in modes of governance, however, is now widely debated. The predominant thesis that there should be a unique and universal set of managerial rules neglects the diversity of national experiences and the heterogeneity of firms. Moreover, evidence and analytical results show that such a unique model tends to generate major failures and turbulences.

Thus, different types of rules have been proposed to govern firms that differ in size, type, industry of origins, and stages of development (Krafft and Ravix 2005; Lazonick and O’Sullivan 2002).

**FIRST-PAST-THE-POST**

The “first-past-the-post” (FPTP) electoral system, or “plurality system,” produces a one-party government as a result of nationwide elections in single electoral districts to
form a national parliament. In existence since the twelfth century, FPTP is the oldest electoral system in political history. It can be found worldwide in thirteen countries, including the United Kingdom, the United States, Canada, India, Bangladesh, Jamaica, Malawi, Mongolia, Nepal, Pakistan, Papua New Guinea, Thailand, and Zambia. The ideal type of FPTP is the British electoral system, the so-called “Westminster model.”

One important advantage of FPTP is its simplicity. First, FPTP divides the whole territory in single-member districts with candidate ballots. Within each constituency, voters cast a single ballot for one candidate rather than for a party. Another advantage of FPTP is constituency representation: Every voter knows the local member of parliament and has direct access to political representation, which is evenly distributed over the country. The candidate with the highest number of valid votes in a given district is elected. He or she is the “first past the post” in the race between candidates on election day in a specific constituency.

Candidates for a seat in the national parliament need neither a minimum threshold of votes nor an absolute majority within their constituency; instead, the candidate with the plurality of the vote wins the seat in question. He or she needs just one vote more than the candidate in second place in the FPTP race. One main disadvantage of FPTP is poor party system representation. For example, in the U.K. model, FPTP has the tendency to favor major parties such as Labour and Conservative and to weaken small parties such as the Liberal and Green parties.

Within the framework of the FPTP electoral system, the translation of votes at general elections to seats in Parliament and the formation of a national government are not based on the share of the national vote, but on the share of parliamentary seats. Since 1935, every British government has been formed on the basis of a minority of the vote, with less than 50 percent of electoral support. Hence, the FPTP electoral system has been described as a “plurality system,” in contrast to a majority system; in fact, it is sometimes called a “single member plurality system” (SMP). The party with the highest number of winners of parliamentary seats forms a one-party government.

Another advantage of FPTP is the stability of the newly elected national government in particular, and of the political system in general, in contrast to coalition governments that might fall apart before the end of the parliamentary term. A further advantage is the speed of the political process: FPTP encourages a quick formation of a new government, avoiding lengthy interparty negotiations necessary to form a coalition government, and the single party in government with a clear majority of seats in parliament is able to decide and implement laws more quickly. A political system that uses FPTP as electoral law is normally stable, fast, and efficient, and displays a high degree of accountability for its actions and public policy.

**FISHER, IRVING**

1867–1947

Irving Fisher, the outstanding American neoclassical economist of the first half of the twentieth century, was born in Saugerties, New York, on February 27, 1867, and was living in New Haven, Connecticut, when he died on April 29, 1947. Fisher graduated with an A.B. in 1888 and a Ph.D. in economics and mathematics in 1891 from Yale University (from which his father, a Congregational clergyman, had also graduated). He taught at Yale until his retirement in 1937, initially in mathematics and then, from 1895, in political economy, and was promoted to full professor in 1898. A student of both the mathematical physicist Josiah Willard Gibbs and the political economist, sociologist, and social Darwinist William Graham Sumner, Fisher combined his interests in mathematics and economics in his dissertation and his first book, *Mathematical Investigations in the Theory of Value and Prices* (1892; Fisher 1997, vol. 1). This remarkable work made Fisher, along with John Bates Clark and Stuart Wood, a pioneer in introducing marginal utility and marginal product analysis into U.S. economics. Fisher’s (re)discovery of both general equilibrium analysis and indifference curves (requiring only a preference ordering, not cardinally measurable utility) was an independent breakthrough because he did not read either Léon Walras or F. Y. Edgeworth until his thesis was almost finished. But modern opinion is consequently divided between Paul Samuelson’s modest description of Fisher’s thesis as
the greatest doctoral dissertation by an American econo-
mist, and Robert Dorfman’s belief that it should have
been rejected for unnecessary reinvention of existing the-
tory. The unique contribution of Fisher’s thesis was his
construction, in an age before electronic computers, of a
hydraulic model simulating the determination of equili-
rium prices and quantities (William Brainard and Herbert
Scarf in Dimand and Geanakoplos 2005). In an article in
1896 Fisher used a simplified hydraulic model to analyze
the bimetallic controversy in monetary economics (Fisher

Fisher’s 1896 American Economic Association mono-
graph Appreciation and Interest (Fisher 1997, vol. 1) attrib-
uted the difference between interest rates expressed in two
standards (gold, silver, paper currencies, or commodities)
to the expected rate of appreciation of one standard
against the other. The Fisher equation, now expressed as
equating nominal interest to the sum of real interest and
expected inflation, formalized an insight briefly remarked
upon by John Stuart Mill and Alfred Marshall. Fisher’s
monograph introduced uncovered interest parity for
exchange rates and the expectations theory of the term
structure of interest rates—that is, differences in interest
rates for different lending periods reflect expected changes
in the purchasing power of money. In The Theory of
Interest (1930; Fisher 1997, vol. 9), Fisher tested his equa-
tion empirically by correlating nominal interest with a
distributed lag of past price level changes (adaptive expec-
tations), finding considerably less than perfect correlation.

Having shown in Appreciation and Interest that cor-
rectly anticipated inflation would affect only nominal
interest, leaving real interest unaltered, Fisher and Harry
G. Brown argued in The Purchasing Power of Money
(1911; Fisher 1997, vol. 4) that, in the long run, a change
in the quantity of money would change the price level in
the same proportion, with no lasting effect on real vari-
ables. Fisher thus defended the quantity theory of money
against both bimetallists who held that monetizing silver
would have lasting real benefits and some of their hard-
money opponents, notably J. Laurence Laughlin of the
University of Chicago, who denied that changes in the
quantity of money could explain observed changes in
prices. While insisting on the long-run neutrality of
money, Fisher viewed monetary shocks as the force driv-
ing short-run fluctuations in real output and unemploy-
ment: his 1926 International Labour Review article, “A
Statistical Relation Between Unemployment and Price
Changes,” was reprinted in the Journal of Political
Economy in 1973 as “Lost and Found: I Discovered the
8). Fisher’s monetary theory of economic fluctuations
depended on the slow adjustment of expected inflation,
and hence of nominal interest, to monetary shocks.

If changes in the purchasing power of money were
correctly perceived and expected, there would be no booms
or depressions, so Fisher campaigned to educate the public
against the “money illusion,” which provided the title of
his 1928 book (Fisher 1997, vol. 8). He also wished to
neutralize price changes through indexation, and persua-
sed Rand Kardex to issue an indexed bond in 1925. Alter-
atively, fluctuations could be eliminated by avoiding
changes in the purchasing power of money, so Fisher pro-
posed a monetary policy rule (the compensated dollar) to
peg the price level by varying the exchange rate (the dollar
price of gold) to counteract any change in a price index.
This monetary policy rule, eradication of money illusion,
and statistical verification of the quantity theory of money
and of the monetary theory of fluctuations all required an
appropriate price index. When prices rise, a Laspeyres
index with base-year quantity weights overestimates the
price increase, which a Paasche index with current-year
weights underestimates. In The Making of Index Numbers
(1922; Fisher 1997, vol. 7) Fisher advocated, as an “ideal
index” suitable for all purposes, the geometric mean of the
Laspeyres and Paasche indexes, the formula that came
closest to satisfying a list of seven criteria he proposed as
desirable for an index number. (Ragnar Frisch and
Subramanian Swamy later determined that no formula
could satisfy all seven of Fisher’s criteria.) In the 1990s se-
veral governments including the United States adopted
Fisher’s ideal index and issued some indexed bonds.

In The Rate of Interest (1907; Fisher 1997, vol. 3) and
The Theory of Interest, Fisher systematized the neoclassical
theory of how the equilibrium real rate of interest is deter-
mimed by the interaction of impatience (time preference)
and opportunity to invest (the expected rate of return over
costs on new investments). The Fisher diagram, showing
utility-maximizing consumption-smoothing over two peri-
ods, illustrated the Fisher separation theorem between the
time-pattern of income and that of consumption: given
perfect credit markets, consumption in any period depends
only on the present discounted value of expected lifetime
income, not on income in that period. Not only was this
insight the basis for the later permanent-income and life-
cycle theories of consumption and saving, but the Fisher
diagram also proved useful in applications ranging from
international trade to insurance (allocation across possible
states of the world). Ironically, Fisher’s 1907 numerical
example of the possibility of multiple solutions for Böhm-
Bawerk’s average period of production prefigured criti-
cisms of neoclassical capital and interest theory advanced
in the Cambridge capital controversies of the 1960s (and
Fisher’s own concept of rate of return over costs was sub-
ject to the same possibility of multiple solutions).

From 1898 to 1904 Fisher battled successfully to
recover from tuberculosis, which had killed his father. His
heightened sensitivity to the value of health and longevity
led him to advocate health insurance, a federal department of health, and prohibition of alcohol; to coauthor the best-seller How To Live; and to estimate the nation’s human capital at five times the value of its physical capital. It also motivated Fisher’s involvement with the dietary reforms proposed by Dr. Kellogg of Battle Creek and with the “race betterment” schemes of the eugenics movement, including support for the Immigration Restriction Act of 1924 (Fisher 1997, vol. 13). Fisher invented and patented a tent for tuberculosis patients.

Among Fisher’s many subsequent inventions, the Index Visible (precursor of the rolodex) made him wealthy, temporarily, when it was absorbed by Rand Kardex. An enthusiastic “new economy” advocate of the permanence of the 1920s stock boom based on technological breakthroughs, Fisher had a net worth of ten million dollars before losing all of it, and more, in the Wall Street crash that began in October 1929. Fisher’s memorable statement that month that “stock prices appear to have reached a permanently high plateau” continues to haunt his reputation with the general public. Among economists, however, after a period of eclipse by the rise of Keynesian macroeconomics, Fisher is now once again celebrated as America’s outstanding scientific economist of the first half of the twentieth century, and perhaps of any time.

Robert W. Dimand

**FISHING INDUSTRY**

The modern fishing industry, with fleets of large capital-intensive vessels, can be traced back to the introduction of the trawler early in the twentieth century. Those ships enabled fishers to reach distant fishing grounds more quickly, stay out fishing longer, and catch more fish per trip. Subsequent growth in the number, size, and technological sophistication of trawlers steadily increased harvesting capacity and corresponding pressures on fish stocks. The introduction of “factory” trawlers in the early 1960s allowed even longer and more distant fishing trips and intensified fishing pressure on previously neglected fish stocks.

A little over 130 million metric tons of fish was harvested worldwide in 2003, almost 80 percent of which was for human consumption (United Nations Food and Agricultural Organization 2004). Reversing earlier trends, the output from ocean harvesting remained fairly constant in the early years of the twenty-first century, accounting for almost 60 percent of consumption. Around 7 percent of the harvest comes from inland waters, and the rest comes from aquaculture, most of which is conducted in fresh waters.

Developing countries provide around 70 percent of the total world supply of fish for human consumption, much of which is harvested using traditional small-scale and labor-intensive technologies. The top countries in 2002 were China, Peru, the United States, Indonesia, and Japan in that order, with China harvesting over twice the amount taken by Peru. One-third of global ocean harvesting occurs in the northwestern Pacific, roughly 20 percent in the southeastern Pacific, 16 percent in the northeastern Atlantic, and 15 percent in the western central Pacific. The major ocean stocks, which are harvested largely by factory fleets, are anchovies (a relatively low-value product), pollock, tuna, herring, and mackerel.

In contrast to the marine fishery, aquaculture production grew at an average annual rate of 6 percent per year after 2000, with China accounting for almost 70 percent of world aquaculture production in 2002, followed by India, Indonesia, Japan, and Bangladesh. The most important aquaculture species is carp, followed by various types of higher-value shellfish, such as oysters and clams.

Trade in fisheries products grew 45 percent from 1992 to 2002, and the value of fisheries exports reached $58.2 billion in 2002. Around 90 percent of this trade involves processed (frozen, salted, dried, and canned) fish products. China is the major exporter of fish, followed closely by Thailand and then the United States, Canada, Denmark, and Vietnam. Developed countries purchase over 80 percent of the total dollar value of traded fish products, with Japan accounting for 22 percent of world imports in 2002, followed by the United States (16%), Spain (6%), and France (5%).

**DUAL ECONOMIC STRUCTURE**

Although it is difficult to generalize about the structure of the fishing industry worldwide, the large-vessel fleet is aging and there has been a decline in the number of very
large vessels being added to fleets (United Nations Food and Agricultural Organization 2004). Large factory vessels and distant-water fleets account for the majority of the harvest, but around 90 percent of all fishers, most of whom are in Asia, work on small vessels (International Labour Organization 2004). Although much of the small-scale fishing sector uses traditional technologies that limit harvesting to heavily fished near-shore waters, there is a growing group of small to midsize vessels with advanced technologies that can access more abundant offshore stocks that can be brought to market quickly enough to command premium prices for fresh fish.

COMMON PROPERTY ISSUES

The fishing industry represents a classic example of the common property problem. Unlike land-based agriculture, ocean fish stocks are a resource for which individuals traditionally do not hold property rights. There is a substantial literature documenting how, in the absence of ownership or regulation of fishing stocks, economic incentives motivate the owners of individual vessels to overfish the resource by harvesting as many fish as possible as quickly as possible (Anderson 1986).

Technological changes that have made harvesting more efficient, coupled with the growth of large-scale fleets and international fish markets, made this common property problem a global concern beginning in the mid-twentieth century. As fisheries stocks become depleted, the scarcity of fish drives up prices, and harvesting incentives become even stronger, threatening the sustainability of the resource. As a result, many of the world’s fish stocks have been classified as having been fished beyond sustainable levels and concerns are being raised about the possible extinction of overfished species.

One response to depleted stocks has been to shift fishing efforts to previously underutilized species. However, experience has shown that those species soon become threatened and that the shifting species mix can have adverse effects on the ecosystem. A second outcome has been the rapid growth of aquaculture, much of which is conducted in areas where property rights can be established, but that has added to the growing concern about environmental pollution in marine and inland waters and its impact on the safety of fish products for human consumption.

REGULATION OF THE FISHING INDUSTRY

Economists have argued that regulation is the only long-term method to achieve the biological, economic, and environmental sustainability of the fishing industry. They also have advocated a form of regulation that relies heavily on markets and property rights to counter common property problems. In practice, however, fisheries regulation has relied on indirect methods to reduce incentives for overfishing.

Initially, the most widely adopted policy was to reduce the access of large-scale foreign fishing fleets to continental fishing stocks to conserve the stocks for domestic fishers. Many coastal nations imposed limits on distant-water fleets in the 1970s by establishing Exclusive Economic Zones (EEZs) that extended territorial control over ocean resources up to 200 miles from their coastlines. The result in many cases, however, was that domestic fleets with increasingly sophisticated harvesting technologies took the place of foreign fishing vessels, and so the pressures on fish stocks continued to increase.

Thus, the focus of national regulatory policies shifted to fishing pressures within EEZs. The most common policy instruments have involved indirectly limiting harvesting activity through seasonal or permanent closures of fishing grounds, reducing fleet size by limiting entry and offering vessel buyouts, and raising the costs of fishing by constraining harvesting technologies, for example, limiting vessel size and power, increasing the minimum mesh size of nets, and reducing the number of days of fishing allowed. Those policies, however, often have proved costly to monitor and easy to evade, allowing overfishing to continue.

As a consequence, pressures have increased to restrict harvesting further. In the United States the 1996 and 2006 reauthorizations of federal fisheries management legislation were designed to force regulators to set allowable harvesting levels lower than the previous levels. The new levels are below what would be needed to ensure biological sustainability to take into account both the environmental and the economic costs of harvesting fish.

Although most management regulations continue to rely largely on indirect regulation of fishing effort, there has been increasing international interest in individual transferable quotas, one of the policies most often advocated by economists. The individual transferable quota policy involves allocating shares (quotas) of the allowable harvest that can be bought or sold. Ownership of a share gives a fisher a property right to a portion of the allowable harvest that essentially privatizes the resource and eliminates the incentive for fishers to compete for the same common stock of fish. Such market-based regulation can both reduce overfishing pressures and ensure the overall efficiency of the industry.

Regardless of the management methods adopted, there has been movement worldwide toward establishing stricter fisheries management controls that are intended to protect fish stocks more aggressively from the threat of extinction. As fish continue to play a major role in world trade and the food supply, most fisheries biologists and economists believe that continued vigilance is required to
ensure that this resource remains available for future generations by using fishing methods that are economically sound and environmentally sustainable.

**FIXED COEFFICIENTS PRODUCTION FUNCTION**

A production function associates the maximum level of output producible with given amounts of inputs. If the inputs must be combined in fixed proportions, like the ingredients of a recipe in a cookbook, the function is a fixed coefficients production function. It is also called a Leontief function, after its inventor, the economist and Nobel Prize winner, Wassily Leontief. Call centers require a one-to-one proportion between workers and telecommunications equipment. Denoting the input quantities by $L$ and $K$, the isoquants are L-shaped (with the kink on the 45 degree line).

To introduce the formal definition, denote the quantities of inputs required per unit of some output by $a_1, \ldots, a_n$, where $n$ is the number of inputs. These so-called input coefficients constitute the recipe or technique for the production of the output considered. Denote the available amounts of inputs by $x_1, \ldots, x_n$, respectively. Then the attainable level of output is given by $y = \min \{ x_1/a_1, \ldots, x_n/a_n \}$. This is the defining formula of the fixed coefficients production function. The inputs for which the minimum value is assumed are called the bottlenecks.

The fixed coefficients production function is the cornerstone of input-output analysis, the quantitative economic tool developed in 1936 by Leontief, who traced the origin to Francois Quesnay's *Tableau Économique* of 1758. Scholars Heinz Kurz and Neri Salvadori described the roots of input-output analysis in detail in their 2000 work, and the theory is expounded in Thijs ten Raa’s *Economics of Input-Output Analysis* (2005). The fixed coefficients function is popular, because only a single observation is needed to calculate it, making use of the input coefficients $a_i = x_i/y$. The connection between fixed coefficients and input-output analysis is as follows.

Since inputs are produced (such as electricity) or non-produced (such as labor services), we may label them $1, \ldots, m, m+1, \ldots, n$, where the last $n - m$ inputs are the nonproduced or so-called factor inputs. Denote the input coefficients of output $j$ by $a_{ij}$. The matrix of intermediate input coefficients is $A = (a_{ij})_{i,j=1,\ldots,m}$ and the matrix of factor input coefficients is $B = (a_{ij})_{i=m+1, \ldots, n, j=1, \ldots, m}$. The matrix of factor input coefficients gives the direct factor requirements of products. Post-multiplication of $B$ with the so-called Leontief inverse, $(1 - A)^{-1} = 1 + A + A^2 + \ldots$, yields the matrix of total factor requirements or factor contents of products. The total requirements include the factor requirements of the produced inputs, $BA$, the factor requirements of the produced inputs of those inputs, $BA^2$, etcetera.

---

*Figure 1*
An important application is the Marxian theory of labor values, in which all commodities are produced, directly or indirectly, by labor. Then the factor input coefficients matrix $B$ reduces to a row vector of direct labor coefficients and the total requirements becomes a row vector of labor contents, one for each product. Another application is energy economics. Here the direct coefficients measure the energy used per unit of output and the total coefficients measure the total amount of energy embodied in products. The inclusion of the indirect effects may cause reversals in the energy intensity of products, when the production of an output requires little energy, but much intermediate input of which the production is energy intensive. The inclination of politicians to subsidize goods of which the direct energy requirements are low may therefore be ill conceived.

Input coefficients tend to be fixed at the level of the firm. Indeed, managers know how many workers are needed to operate the machines. Input coefficients vary between firms though and, therefore, the fixed coefficients production function is less appropriate for industries or economies. For example, if the wage rate increases relative to the rate of interest, labor-intensive firms may shut down and capital-intensive firms may expand to full capacity. As a result, the economy will be more capital intensive. Though derived from micro fixed coefficients production functions, the macro production function will thus feature input substitutability, much like the Cobb-Douglas function. In fact, the latter can be derived mathematically if the production capacity across firms follows a Pareto distribution, which is defined by the same formula as the Cobb-Douglas function. Most applied general equilibrium models feature production functions with a mixture of fixed and variable coefficients, but even when all the production functions are of the fixed coefficients variety, the response to price shocks may be the same as in a model with variable coefficients production functions.

**FIXED EFFECTS**

**SEE** Generalized Least Squares.

---

**FIXED EFFECTS REGRESSION**

A fixed effects regression is an estimation technique employed in a panel data setting that allows one to control for time-invariant unobserved individual characteristics that can be correlated with the observed independent variables.

Let us assume we are interested in the causal relationship between a vector of observable random variables $x = (1, x_1, x_2, \ldots, x_N)$ and a dependent random variable $y$ where the true linear model is of the following form:

$$y_i = \beta x_i + \mu_i + \varepsilon_i,$$

with $\mu$ being an unobserved random variable characterizing each unit of observation $i$ and $\varepsilon$ the stochastic error uncorrelated with $x$.

When $\mu$ is correlated with $x$ we cannot consistently estimate the vector of parameters of interest $\beta$ using Ordinary Least Squares because the standard assumption of no correlation between the error term and the regressors is violated. In a cross-sectional setting, typical strategies to solve this omitted variable problem are instrumental variables or the inclusion of proxies for $\mu$. However, when the available data is longitudinal, that is, when it contains a cross-sectional as well as a time series dimension, it is possible to adopt alternative estimation methods known in the literature as "panel data" techniques.

Assuming we repeatedly observe $N$ units for $T$ periods of time, and that the unobservable variable $\mu$ is time invariant, we can write our model as:

$$y_{it} = \beta x_{it} + \mu_i + \varepsilon_{it},$$

with $i = 1, \ldots, N$ and $t = 1, \ldots, T$.

Depending on the correlation between the omitted variable $\mu$ and the regressors $x$, alternative estimation techniques are available to the researcher. A fixed effects regression allows for arbitrary correlation between $\mu$ and $x$, that is, $E(x_{it} \mu_i) \neq 0$, whereas random effects regression techniques do not allow for such correlation, that is, the condition $E(x_{it} \mu_i) = 0$ must be respected. This terminology is somehow misleading because in both cases the unobservable variable is to be considered random. However, the terminology is so widespread in the literature that it has been accepted as standard.

A fixed effects regression consists in subtracting the time mean from each variable in the model and then estimating the resulting transformed model by Ordinary Least Squares. This procedure, known as "within" transformation, allows one to drop the unobserved component.
and consistently estimate \( \beta \). Analytically, the above model becomes
\[
\tilde{y}_i = \beta \tilde{x}_i + \tilde{\varepsilon}_i
\]
where \( \tilde{y}_i = y_{it} - \tilde{y}_i \), with \( \tilde{y}_i = T^{-1} \sum_{t=1}^{T} y_{it} \) (and the same for \( x_i, \mu_i, \) and \( \varepsilon \)). Because \( \mu_i \) is fixed over time, we have \( \mu_i = \tilde{\mu}_i = 0 \).

This procedure is numerically identical to including \( N - 1 \) dummies in the regression, suggesting intuitively that a fixed effects regression accounts for unobserved individual heterogeneity by means of individual specific intercepts. In other words, the slopes of the regression are common across units (the coefficients of \( x_1, x_2, \ldots, x_K \)) whereas the intercept is allowed to vary.

One drawback of the fixed effects procedure is that the within transformation does not allow one to include time-invariant independent variables in the regression, because they get eliminated similarly to the fixed unobserved component. In addition, parameter estimates are likely to be imprecise if the time series dimension is limited.

Under classical assumptions, the fixed effects estimator is consistent (with \( N \to \infty \) and \( T \) fixed) in the cases of both \( E(x_{it}, \mu_i) = 0 \) and \( E(x_{it}, \mu_i) = 0 \), where \( j = 1, \ldots, K \). It is efficient when all the explanatory variables are correlated with \( \mu_i \). However, it is less efficient than the random effect estimator when \( E(x_{j t}, \mu_i) = 0 \).

The consistency property requires the strict exogeneity of \( x \). However, this property is not satisfied when the estimated model includes a lagged dependent variable, as in
\[
y_{it} = \alpha y_{i,t-1} + \beta' x_i + \mu_i + \varepsilon_{it}
\]
This suggests the adoption of instrumental variables or Generalized Method of Moments techniques in order to obtain consistent estimates. However, a large time dimension \( T \) assures consistency even in the case of the dynamic specification above.

Sometimes the true model includes unobserved shocks common to all units \( \tilde{a} \), but time-varying. In this case, the model includes an additional error component \( \tilde{\delta}_i \), that can be controlled for by simply including time dummies in the equation.

A typical application of a fixed effects regression is in the context of wage equations. Let us assume that we are interested in assessing the impact of years of education in logs \( \varepsilon \) on wages in logs \( w \) when the ability of individuals \( a \) is not observed. The true model is then
\[
w_i = \beta_0 + \beta_1 \varepsilon_i + u_i
\]
where \( v_i = a_i + \varepsilon_i \). Given that unobserved ability is likely to be correlated with education, then the composite stochastic error \( u \) is also correlated with the regressor and the estimate of \( \beta_1 \) will be biased. However, since innate ability does not change over time, if our data set is longitudinal we can use a fixed effect estimator to obtain a consistent estimate of \( \beta_1 \). Applying the within transformation to the preceding equation we end up with \( \tilde{w}_i = \beta_1 \tilde{\varepsilon}_i + \tilde{\varepsilon}_i \), where we have eliminated the time invariant unobserved component \( a_i \). Being \( E(\tilde{\varepsilon}_i) = 0 \), the model now satisfies the classical assumptions and we can estimate it by Ordinary Least Squares.

BIBLIOGRAPHY

Luca Nunziata
an increase in money growth in the presence of rigid prices may have real effects on the economy. However, in the long run, prices are flexible and an increase in money growth translates into an identical increase in the rate of inflation, with no effects on unemployment and output.

Prices are characterized by different degrees of flexibility, even in the short run. For instance, stock prices adjust very quickly to changes in market conditions, whereas wages—that is, the price of labor—adjust much more slowly. Wage rigidity can be explained by the staggering of wage contracts, by the role of unions in the wage bargaining process, or by the firms' willingness to pay real wages above the equilibrium level in order to attract and maintain the best workers or to reduce shirking (efficiency wage theory).

Economists often use the notion of flexibility when describing labor markets in which firms are free to vary the amount of labor they use in production, for example through dismissals when they are hit by a negative shock. A broader definition of labor market flexibility involves the institutional features that may induce a deviation of labor market outcomes from the perfect competitive equilibrium. A flexible labor market is then characterized by minimal regulations in terms of dismissal costs (or employment protection legislation) and labor standards, limited unemployment benefits, no minimum wages, low taxation, and a marginal role for trade unions. But the dichotomous concept of flexibility (versus rigidity) applied to labor markets can be misleading. Indeed, it does not help in distinguishing the continuum of potential social models, each characterized by a certain degree of flexibility and/or rigidity in certain institutional dimensions.

Each labor market regulation may be rationalized on the basis of political economy considerations. It may also have desirable social and economic purposes. For example, a reasonable degree of employment protection may induce higher productivity if workers decide to invest more in firm-specific skills; a reasonable level of unemployment benefits contingent on effective job search may help smooth consumption patterns in the presence of negative idiosyncratic shocks and financial markets imperfections. However, if employment protection is too strict, firms may be reluctant to hire new workers during economic expansions because it would be more costly to dismiss them during contractions. The negative burden of the rigidity would then fall on new labor market entrants, who would find it harder to be hired in the first place (insider-outsider theory). A flexible labor market, in contrast, would adapt more easily to positive as well as negative shocks. This might result in a larger variance of employment along the business cycle, with ambiguous effects on average employment, but possibly a more efficient allocation of labor in the long run.

FLOW
Embedded within and critical to the burgeoning field of positive psychology, the concept of flow represents an optimal state of consciousness, a positive psychological state. The American psychologist Mihaly Csikszentmihalyi (1990), who devised the concept of flow, describes how this experience helps promote creativity and psychosocial complexity. The study of flow began following interviews Csikszentmihalyi (1975) conducted with artists, mountain climbers, athletes, chess players, and surgeons, where a high level of consistency was found in descriptions of how things felt when their activity was going really well. Flow occurs when one is engaged in activities one enjoys and that extend one's capabilities.

Flow is an optimal state because it involves a fully focused mind. When in flow, nothing disturbs or detracts from this concentrated state. Neither external nor internal distractions take up mental space. This total focus on the task at hand is a defining feature of flow. It is one of the several dimensions comprising flow, as described below:

1. **Challenge-skill balance.** In flow, there is a perception of capability for the demands of the task one is engaged in. Described by Susan Jackson and Csikszentmihalyi (1999) as the golden rule of flow, this perceived balance between challenges and skills is the necessary precondition for flow to occur.
2. **Action-awareness merging.** When in flow, action follows action easily, sometimes providing a sense of automaticity of movements. This sense of oneness, or merging of the self with the activity, results from the total task focus of flow.
3. **Clear goals.** The person in flow knows clearly what it is he or she wants to do, and this clarity of purpose guides the person from moment to moment.

4. **Unambiguous feedback.** Flow provides clear feedback regarding task performance in relation to goal accomplishment. Immediate and clear feedback allows for adjustments to be made as required to ensure that one's performance matches one's goals.

5. **Concentration on the task at hand.** A defining feature of flow, a centered mind, provides the internal environment for the other flow dimensions.

6. **Sense of control.** When in flow, there is no worry about potential loss of control. This freedom from worry over control is a liberating state.

7. **Loss of self-consciousness.** In flow, there is freedom from self-consciousness. Instead of worrying about how one appears to other people, one is absorbed with processing information about the task at hand.

8. **Time transformation.** Often, but not always in flow, time drops from awareness. This results in perceptions of altered time. Generally, the sense is that time speeds up, akin to the adage that time flies when one is having fun.

9. **Autotelic experience.** The term autotelic, from the Greek words auto (self) and telos (goal), has been defined by Csikszentmihalyi as an experience that is intrinsically rewarding. This dimension is the end result of the other flow dimensions. Being in flow is an enjoyable experience, and once attained, the motivation is high to return to a flow state.

These flow dimensions work together synergistically to create an optimal psychological experience. In lay terms, flow can be described as enjoyment, and it provides highlights in one's experience of life. Enjoyment is distinguishable from pleasure according to Csikszentmihalyi (1990). While the latter is associated with satisfaction from having needs met, it is only enjoyment that leads to growth, since enjoyable experiences move one forward and in doing so, require investment of mental energy. There are also positive developmental implications of the flow model. Flow experiences lead to growth in competence and in psychological complexity, through the continually evolving process of matching challenges with skills in an activity. Flow is not an easy state to achieve, with the matching of challenges and skills not a straightforward process in many situations. Both external and internal obstacles can keep flow experiences from occurring. It may be by one's own choosing that negative psychological states are experienced, or the environment one is operating in may foster negative mindsets. While it may be possible to focus through the energy of negativity, flow is a much more conducive state to clear and unfettered attention toward a task, and the enjoyment arising from flow experiences generates continuing motivation toward attainment of goals.

**FLOWER INDUSTRY**

Since the 1980s, there has been a consistent increase in the global demand for fresh cut flowers. While such flowers were previously purchased only by upper-income households, they have become a regular decorative feature in households with lower incomes. Although a variety of flowers are grown, roses are the most frequently traded, followed by carnations and chrysanthemums. The feminization of labor is deeply entrenched in the flower industry, which is characterized by high levels of young female employment. Women tend to occupy 60 to 90 percent of the jobs in the labor-intensive stages of flower production.

The commercialization of flowers began in Western Europe when the demand for tulips reached an all-time high in the middle of the seventeenth century. This triggered a massive speculation for tulips called the Great Tulip Mania. However, evolution of the flower industry into a global modern economic sector can be traced back to the 1970s. Prior to that, flower production was almost exclusively for consumption in the regions where it was produced. Production was also concentrated in the developed countries, and flowers were almost exclusively produced in the Netherlands, Japan, and the United States, which accounted for nearly 75 percent of production. While flowers produced in the United States and Japan were largely consumed locally, the Netherlands' production served the European regional market. By the 1980s, however, developing countries, particularly in Africa and Latin America, had begun producing cut flowers for the global export market. The Netherlands, however, still remains the largest flower consumer, exporter, and producer globally. Virtually no fresh flowers were imported to
the United States before 1960, but the U.S. demand is now increasingly being met by imports from Latin America. California is the largest flower producing state, accounting for about 66 percent of U.S. production.

At the beginning of the new millennium, total global acreage allocated to flower production was 200,000 hectares, with the three main producing countries being the Netherlands, United States, and Japan. Germany is the largest of the six importing countries, followed by the United States, the United Kingdom, France, the Netherlands, and Switzerland, which account for nearly 80 percent of global imports. The expansion of commercial production of flowers in developing countries has catapulted the African, Caribbean, and Pacific regions into the global market as key players.

The changing nature of product varieties, production techniques, markets, and retailing arrangements also characterize the flower industry as a highly dynamic sector. The traditional point of sale for flowers has historically been florist shops, but these retailers are increasingly losing their customers to supermarkets and discount stores. Simultaneously, the Netherlands’ flower auctions, where the majority of flowers exported to and from Europe are traded, are being bypassed by supermarkets that buy large volumes of flowers directly from producers. With so many new sources of supply, intense competition has set in, leading to a downward spiraling of prices, particularly for roses. At the same time, the quality imperatives of the market have increased costs of production. Typically, costs of production tend to be pushed down to workers, most of whom work in precarious conditions—many are hired on a casual, low-paid basis, with no employment contracts and frequent exposure to pesticides.

The shift of flower production to the developing countries has increased worker exploitation and pesticide poisoning. In addition to the health hazards that the pesticides pose, the runoff of pesticides and fertilizers into streams and aquifers threatens already fragile water resources. As the industry becomes increasingly globalized, concerns are being raised about its social and environmental impacts. Having been the target of civil-society campaigns and media exposés for poor labor practices and environmentally damaging production processes, however, the industry appears poised to operate in a more socially and environmentally responsible manner. Flower producers now have to comply with a number of codes of conduct developed by their major market brokers, international organizations, and national industry associations.

FLYNN EFFECT

The term Flynn effect refers to the worldwide phenomenon of markedly increasing mean performance on standardized IQ tests over time. Most current IQ tests are designed to have a population mean of 100 and a standard deviation of 15 at the time they are developed. The mean and standard deviation are set by administering the test to a large group of individuals designed to be representative of the population as a whole (a process referred to as “standardization” or “norming”). However, a growing body of evidence suggests that the mean population performance on IQ tests has improved markedly over the decades since they were first introduced in 1905. Over a period of several years after an IQ test is introduced, the test’s mean of 100 becomes obsolete and IQ scores become elevated overall. Periodic renorming of IQ tests (typically at twelve- to twenty-five-year intervals) have helped mask the magnitude of this IQ increase. To compensate for improvements in performance over time and to ensure that the mean score is 100, individuals in the standardization group for a newer IQ test typically have to answer more (or harder) questions to obtain the same score on the new test as on an older test.

The degree and scope of the phenomenon of improved IQ test performance was not broadly known until James Flynn (b. 1934), a political scientist at the University of Otago in New Zealand, wrote two seminal articles on the topic that appeared in Psychological Bulletin in 1984 and 1987. Flynn reviewed dozens of studies in which groups were administered two or more IQ tests that were standardized at different times. Flynn noted that in these studies the groups’ mean performance on a test with newer standardization samples was nearly always lower than their performance on a test with older standardization samples.

Flynn has estimated the size of the Flynn effect on the Wechsler and Stanford-Binet series of IQ tests (the most...
Flynn Effect

widely used IQ tests in the United States) as being at about 3 points per decade or about .3 points per year (Flynn 1984, 2006). This rate of improvement has been remarkably consistent across different time periods and tests within these series. However, the rate of improvement is not uniform across all varieties of IQ tests, or even on subtests within a particular IQ test. The largest gains (.5 points per year or more) have been found on Ravens Progressive Matrices, a nonverbal pattern recognition IQ test. Lowest gains (near 0 points per year) have been on Wechsler Verbal IQ subtests such as vocabulary, information, and arithmetic.

Because of the time and cost involved in administering standardized IQ tests, they are typically administered only to students who are being considered for special education or gifted and talented programs. The Flynn effect has been found to particularly affect the educational classifications of students who are being tested for eligibility for these services shortly before and after a revised IQ test comes out. The impact of the Flynn effect on children being tested for mental retardation services in the early 1990s was quite substantial. The IQ criterion for mental retardation is typically an IQ of 70 or below, which is two standard deviations below the mean of 100 on current IQ tests (allowances for measurement error typically permit a score of up to 75). When the Wechsler Intelligence Scale for Children–Third Edition (WISC–III) supplanted the Wechsler Intelligence Scale for Children–Revised (WISC–R) in 1991, the test norms for the WISC–R were nineteen years old. Tomoe Kanaya, Matthew Scullin, and Stephen Ceci (2003) found that children in the mild mental retardation and borderline IQ ranges scored more than five points lower on the WISC–III than on the WISC–R, which is similar to what was found with children in the average range of intelligence. This five-point difference in scores more than doubled the number of children who were eligible for mental retardation services on the basis of their IQ scores. This is because about 2.27 percent of children would be expected to obtain an IQ score of 70 or below on the WISC–III at the time of its standardization, whereas the obsolete WISC–R was only capturing the bottom 0.87 percent of children by 1991. Scullin (2006) found that in forty-three states and in the United States as a whole, a long and steady decline in the percentage of schoolchildren receiving mental retardation services during the 1980s and early 1990s ended and indeed reversed around the time of the introduction of the WISC–III.

As the norms of an IQ test grow older, the Flynn effect increases the number of children eligible for learning disability services in areas in which the criterion for eligibility is a significant discrepancy between children's IQ scores and their performance on an achievement test. Higher IQ test scores relative to achievement result in an increased likelihood of finding a significant discrepancy. Similarly, more children become eligible for gifted and talented programs over time as it becomes easier to meet the criterion. Once a newly standardized test is introduced, these trends reverse themselves and it becomes harder to meet the IQ–achievement discrepancy criterion for learning disability and the IQ threshold for gifted and talented services.

As documented by Ulric Neisser (in The Rising Curve, 1998), the Flynn effect raises some important nature vs. nurture questions about the relative strength of genes and environment in determining intelligence, and about IQ as an estimate of intelligence. The Rising Curve was written in response to Richard Herrnstein and Charles Murray's best-selling book The Bell Curve (1994), in which the authors argued that intelligence is assessed well by IQ tests and that low IQ is related to a wide range of negative life outcomes, from criminality to risk for divorce. Herrnstein and Murray used behavioral genetics data to make a case for a strong genetic influence on IQ, including ethnic differences in mean IQ scores. Neisser counter-argued that IQ scores have been increasing at too rapid a rate to be explained by genetics alone, which suggests that there are strong environmental influences affecting IQ scores. Neisser's book noted that possible non-genetic explanations for the Flynn effect include increasing environmental complexity, new schooling techniques, and improvements in nutrition.

Just as there is no consensus about the origins of the Flynn effect, there is conflicting evidence about whether the Flynn effect is continuing unabated. In the United States, comparison study data for the Wechsler Adult Intelligence Scale–Third Edition (standardized in 1995) suggested that perhaps the rate of IQ increases in the United States was diminishing. Longitudinal data from IQ-test–like draft-board examinations of all draft-eligible males in some European countries also documented a leveling-off of IQ score gains during the 1990s. However, data from comparison studies for the Stanford-Binet Intelligence Scale–Fifth Edition and Wechsler Intelligence Scale for Children–Fourth Edition (both normed around 2001) suggest that the best estimate of the rate of IQ test improvement in the United States is currently still around .3 points per year (Flynn 2006).

FOGEL, ROBERT

1926–

Robert Fogel is an economist and economic historian who has been a pioneer in the application of quantitative methods and economic theory to the measurement of long-term economic change. His work has stimulated and provoked historians, and he has argued for the value of mathematical and quantitative tools in the study of demographic, political, and social history as well as economic history.

Robert William Fogel was born in New York City on July 1, 1926. His parents were refugees from the Russian Revolution. After attending public school in New York, he began his undergraduate studies at Cornell University in electrical engineering. However, his awareness of the problems of unemployment in capitalist economies led him to switch his major to history with a minor in economics. He graduated in 1948, and in the early 1950s he worked as a Communist Party organizer.

In 1956 Fogel began graduate work in economic history at Columbia University, with a particular interest in the great Marxian questions concerning the nature of long-term economic change. He moved to Johns Hopkins University for doctoral research in order to pursue a quantitative approach to the study of economic growth under the direction of Simon Kuznets. He began his teaching career at Johns Hopkins as an instructor in 1958, before taking an appointment as assistant professor at the University of Rochester in 1960. In 1963 he moved to the University of Chicago, and between 1975 and 1981 he taught in Harvard’s Economics Department. He was instrumental in the late 1970s in establishing the Development of the American Economy (DAE) program associated with the National Bureau of Economic Research. In 1981 he returned to the University of Chicago to become the Walgreen Professor of American Institutions and the director of the Center for Population Economics. Fogel’s radical political activity as a young adult presents a striking contrast with the anti-Communist origins of the Walgreen chair. His occupancy of the chair can be interpreted as reflecting both his own movement toward the political center and the latitude the Walgreen family gave the University when the chair was offered to him. In 1993 he was awarded the Nobel Memorial Prize in Economic Sciences (shared with Douglass North) for the development of quantitative and theoretical tools for the study of economic history.

Fogel’s early work focused on the determinants of American economic growth. His doctoral dissertation, and the subsequent book Railroads and American Economic Growth: Essays in Econometric History (1964), challenged the prevailing view that the railroad had a decisive influence on the growth of the American economy. He calculated how much higher the costs would have been to the U.S. economy in 1890 of providing the same level of transportation services with alternative modes of water and land transportation. Fogel’s counterfactual methodology proposed a hypothetical canal system that would have been built in the absence of railroads. His estimated “social saving” of the railroad was less than 5 percent of 1890 U.S. gross national product. Fogel’s findings spawned numerous challenges by other scholars. Fogel responded by arguing that, for the case of the United States, any plausible allowance for factors raised by critics (such as scale effects and problems of measuring freight rates on rail versus water traffic) would still imply a modest rather than indispensable contribution to economic growth. However, Fogel also acknowledged that for other economies—such as Mexico, with its more limited access to water transport—the impact of the railroad on growth may well have been substantially larger. His counterfactual methodology generated considerable controversy among historians, with some stating that it was fundamentally ahistorical and fictive. Fogel replied that an analytical and causal approach to economic history inevitably requires the posing of counterfactual questions.

Fogel’s next major project was a collaborative effort with Stanley Engerman on the economics of U.S. slavery. In the two-volume Time on the Cross (1974), they came to the surprising conclusion that Southern slave plantations were more efficient than Northern free farms. Critics argued that this finding was due to inadequate allowance for differences in crop mix, land quality, scale, and eco-
nomic aims. Fogel and Engerman maintained that their result held, even with due allowance for these other factors, and they attributed it to the extra work effort that could be coerced from slave gangs. They also argued that slave owners had incentives to protect the capital investments their slaves represented. They supported this conclusion with evidence that slaves tended to be well fed and housed, that they were in fact only relatively infrequently subjected to abusive physical punishment or the breakup of their families through sale, and that female slaves did not engage in unusually high rates of premarital sexual intercourse. Fogel has continued to defend these specific findings against an extensive body of scholarly criticism. However, he has conceded that an appropriate moral indictment of slavery requires going beyond a narrow quantitative economic framework. His later writings on slavery have used a more traditional narrative approach along with the examination of quantitative evidence. Moreover, Fogel employed a mix of quantitative and qualitative approaches to address moral issues in The Fourth Great Reawakening and the Future of Egalitarianism (2000).

Since the mid-1970s, Fogel has undertaken the use of large-scale databases, such as Union Army pension records, to study trends, determinants, and the consequences of improvements in nutrition, health, and mortality and morbidity rates. His work (with collaborators) employing evidence on human heights to measure trends in nutrition spawned the burgeoning field of anthropometrics. He has shown how poor nutrition and health in early childhood can have enduring consequences for health later in life.

The Royal Swedish Academy of Sciences awarded the Nobel Prize jointly to Fogel and North in 1993, recognizing that both scholars have shown how economic history can provide fundamental insights into processes of economic and institutional change. The academy noted that North's contributions have been primarily conceptual, while Fogel is an empiricist. North has been circumspect about prospects for human progress after making allowance for the contingencies of political processes and mistakes in human judgement. Fogel, however, is an unabashed optimist about the prospects for human material progress, though he acknowledges the ongoing presence of spiritual and ethical challenges. He has coined the term technophysio evolution to point to the interaction between technological and human physiological advances.

FOOD

Food is a biological necessity. Like sex, it has implications for the perpetuation of the species, but unlike sex, it also has implications for the survival of each individual. Social anthropologists point out that food is further implicated in the social and cultural survival of human groups. Acquiring and eating food is thus extended into the realms of the economic, political, and psychological.

Human beings are omnivorous, capable of safely eating a particularly wide variety of plant and animal sources of nutrients—a characteristic that has enabled the worldwide distribution of the species. Major, very broad transitions in human modes of living can be traced. Some 10,000 years ago the protracted shift began from foraging—continually on the move, hunting and gathering—to farming—settling, domesticating plants, and tending livestock. Then there is the comparatively recent 500-year increase in the movement of both people and foodstuffs around the globe: for example, new people to the Americas, turkeys to Europe. Most recently is the approximately 200 years’ industrialization of both food production—agriculture, preservation, and processing—and food consumption—wholesale and “ready-made” retail distribution—that has been coupled with and supported by the increasingly intense application of physical, chemical, and biological sciences. The role of food in this long history of human groups is shrewdly summarized by Raymond Firth, who observed...

FOLKLORE

SEE Ethnology and Folklore.
that in industrial society, getting food occurs in breaks between work, whereas in nonindustrial society, getting food is the day’s work (1973).

The contemporary supply and distribution of food worldwide is notoriously unequal and inequitable. Particular attention has been devoted to international policies for the relief of severe and devastating food shortages. A major theme of this work is to note serious disjunctions that have profound consequences for those whose plight is meant to be alleviated. On the one hand are the media images of famine conjured in more-developed countries, typically of children in profound distress—images that then get dovetailed with assumptions embedded in international agencies’ debates on world food security as to the relief required. On the other hand are what Johan Pottier describes as the everyday realities food-insecure people face (1999). In The Anthropology of Food he includes a simple, but compelling example. Official agricultural programs had no space in their information-gathering exercises in Kenya for the testimony of an elderly woman farmer, reputed in her community to be the most knowledgeable about growing yams. The program was, “top down,” informed by research scientists’ knowledge, not local expertise.

Even desperately hungry people need “their own” food, because, despite being omnivores, people do not eat everything available that is nontoxic and nutritious. This observation is only partly explainable in biological terms. Human groups the world over are observed to be selective in what, culturally speaking, counts as food. Such social definitions of food vary from society to society and they change over time. Familiarly, horse meat is food in Belgium but not in the United States; dog is a delicacy in parts of China but not in France. And on their first introduction to England, tomatoes were regarded as attractive but poisonous, whereas potatoes were initially grown in Sweden only as a garden ornament.

The social definition of food extends to encompass whole cuisines—distinctive combinations of ingredients and modes of their transformation into dishes—and what has been called culinary culture, a shorthand term for the ensemble of attitudes and tastes (both literal and metaphorical) members of a social group bring to cooking and eating food they have selected. Certain cuisines and culinary cultures have a long and persistent history. The beginnings of a Japanese rice-based cuisine, for instance, can be dated from the introduction of wet-rice agriculture over 2,000 years ago. Rice features strongly in eighth-century myths seeking to establish a national identity distinguishing Japan from its neighbors. These stories entailed notions of abundance, a land of good rice harvests. Divine power was incorporated into every grain of rice, symbolizing not only the relation between deities and people, but also of those among human beings themselves. Thus rice became central to commensality, the act of eating together, and thereby cemented and symbolized social relationships—and a meal without rice could not count as a meal.

The case of rice illustrates the manner in which some have stressed the prime significance of symbols in understanding culinary cultures. By contrast, others have argued that emphasizing the material and practical rather than the symbolic offers superior intellectual interpretations of the variability in social definitions of food. But in a study of the global reach of sugar over four centuries, Sidney Mintz presented a powerful case for a combined approach that recognizes the symbolic significance of a foodstuff while arguing that meaning thus attributed is a consequence of practical human activity (1985). That the meaning of sugar could change from medicine in late-medieval Europe to luxury (like a spice, available only to the exceptionally wealthy) in the early modern period, then to a commonplace necessity to the laboring classes of nineteenth-century Britain, occurred, Mintz argues, as a result of usage—and of supplier-induced demand.

The case of rice also introduces the idea of a proper meal—one that is culturally appropriately composed, prepared, and served on socially prescribed occasions—a version of which appears to be found in most human groups. A British version—the caricatured “meat and two vegetables”—continues to be readily detectable not only in Britain, but also in its erstwhile colonies in North America, southern Africa, and Australia. Scholars specializing in the study of late twentieth- and early twenty-first-century consumption have claimed, however, that allegiance to such “traditional” modes of eating are disappearing, as part of broader changes of postindustrial society. One element of such changes, they argue, is the proposal that social differentiation is diminishing: No longer are education, income, gender, or age systematically evident in preferred dishes, locales for eating (e.g., expensive restaurants or fast-food diners), or the household division of food-preparation tasks. Another is that the predominant mode of food provision in both household and public settings has become commercial rather than domestic: Coupled with an increase in the rate of eating away from home in cafés, restaurants, and diners is the use at home of ready-made complete meals rather than dishes prepared from raw ingredients. And a third element—finding frequent expression in popular and journalistic commentaries claiming that families no longer gather round the table to share a meal—is that institutional rhythms are subject to erosion. Substantiating these claims adequately is difficult, however, and determining the extent to which they apply remains incomplete.

What is clear, though, is that the twenty-first-century food supply is global, providing populations in more
developed countries with year-round fresh produce from less developed countries and an apparently ever widening range of products on supermarket shelves, with consumer choice as a watchword. Critics point to the environmental as well as social costs, for example in the diversion of comparatively limited local supplies of water to agricultural production for export markets, or the additional carbon emissions of air freight. Trends such as this are paralleled by a strikingly rapid increase in rates of obesity in a growing number of countries. Some commentators are even predicting that a generation of children will suffer fatal diseases associated with obesity—for example, diabetes and heart disease—to such an extent that they may even predecease their parents. This kind of public concern looks set to supplant the food-safety scares that dominated the last two decades of the twentieth century, the most dramatic and most costly example of which was bovine spongiform encephalopathy (BSE), commonly called mad cow disease, responsible for an invariably fatal disease if eaten by human beings. Public health policies, especially those geared to limiting the rates of obesity, are not readily aligned with economic policies supporting industrialized food production and the associated provision of employment. This essential, but in its current incarnation highly contested, sphere of human existence represents a considerable intellectual challenge to the still comparatively small number of social scientists seeking to understand its myriad facets.

FOOD CRISIS

The understanding of the causes of food crises, in the history of the social sciences, has evolved, from those stressing “natural” or lawlike causes, to those emphasizing the social nature of such crises. When Thomas Malthus, the English cleric and economist, first wrote his Essay on the Principle of Population (1798), he understood the occurrence of food crises as the effect of lawlike processes, saying that food production grows “arithmetically,” while population grows “geometrically.” This Malthusian view of food crises as basically caused by insufficient production has in modern social science been replaced by an understanding stressing the social causation, both of the occurrence of food crises and of their causes. Seminal in this change of view is the economist Amartya Sen’s Poverty and Famines (1981).

With the development of the division of labor, with food markets extending the local village-town nexus to national and global scale, the occurrence of famine and hunger in principle gets disconnected from the local production conditions and their annual fluctuations. Thus, Sen showed that the Bengali Famine in 1943 was not primarily caused by harvest failures in Bengal, but by wider economic, social, and political conditions pertaining to the colonial economy, the nature of Bengali society, and political conditions during World War II (1939–1945).

When Malthus wrote his Essay, British agriculture was undergoing a major transformation in farming systems, usually referred to as high farming, allowing a much larger nonagricultural population to be fed by a diminishing work force in agriculture. Although this development is reflected in later editions of the Essay, the transformation was not foreseen, nor adequately conceptualized by Malthus.

THE GREEN REVOLUTION

A similar mismatch between the development of food production systems and social scientists’ understanding of them occurred during the Green Revolution. This term refers to the state-driven efforts from the late 1960s forward to increase national self-sufficiency in food grains in a number of Asian countries based on stepped-up investments in agricultural production and research in new crop technologies. For example, the economist Gunnar Myrdal published his Asian Drama in 1968. Typically for its time, the work was pessimistic about the future of an Asia with its high population growth rates. About a year earlier, the Green Revolution was launched, and over a generation, the threat of famine was almost entirely averted in the continent. While Myrdal was unable to foresee this development, younger generations of social scientists have emphasized and often exaggerated the negative distribution and environmental effects of the Green Revolution at the same time as its basic achievements of averting the threat of famine have been downplayed.

Never before and, as far as one can foresee, never again, have the challenges to the world food system been as great as during the second half of the twentieth century. During that period, global production of food grains grew
at rates outstripping those of world population, thus defying Malthusian predictions. This is an obvious background to the shift in scholarly understanding of food crises, from stressing natural or lawlike tendencies to stressing the social dimension.

During the early years of the twenty-first century and despite record levels of world production of grain, approximately 15 percent of the world population was starving or suffering chronic undernutrition. This lack in food security affects the life chances of people, their longevity, and the chances of infants and mothers to survive childbirth. Also health conditions are affected and, in serious conditions of undernutrition, learning capabilities, thus impairing the overall life chances of the individual.

THE GEOGRAPHY OF HUNGER
In the early twenty-first century, the highest incidence of undernutrition (over 35%) was in sub-Saharan Africa, with somewhat lower rates (between 20 and 35%) in the Sahel region of Africa, in parts of South and Central America, and parts of South, Southeast, and Central Asia. In a country like India, widespread undernutrition co-existed with a huge surplus of grain in government stocks, emphasizing the social causation of hunger.

Since decolonization in the 1960s, food production in sub-Saharan Africa grew steadily, but did not keep pace with the growth of population. As a consequence, the dependence of the subcontinent on imported food likewise grew. Again, stressing the complicated causation of food crises, many scholars argued that the import of cheap grain damaged African food production systems. Surplus stocks were dumped on world markets by the United States and the European Union and contributed to the insufficient growth of domestic production and thus to the food crisis in Africa.

There is an easily traceable influence from the world community of social scientists on the definition of food crisis and thus on the general evolution of agricultural policies. The support to the political project of a Green Revolution in the West, at the time, was inspired by a Malthusian view of the population-food nexus and by a fear, during the cold war, that widespread hunger would lead to the spread of communism in Asia. Not only the Malthusian assumption, but also the assumption that hunger breeds radicalism, has been largely discredited by social science. Victims of food crisis are seldom radical and more often meek, apathetic, and subservient.

FROM FOOD CRISIS TO FOOD SECURITY
In tandem with the shift of focus from production to distribution, and from food crisis to food security, the political emphasis shifted both in national governments as well as in global organizations like the United Nations’ Food and Agriculture Organization (FAO), its World Food Program (WFP), and the International Fund for Agricultural Development (IFAD). During the late 1990s, this shift in attention may have partly caused and at least legitimated the declining levels of aid going to the agricultural sector. In the early years of the twenty-first century this trend appeared to be broken, partly as a result of increased focus on world hunger in connection with the millennium shift, but perhaps partly due to a realization among policymakers and social scientists that the focus on issues of distribution should not be permitted to lead to the neglect of production. Without production there is obviously nothing to distribute.

Food Diplomacy
Food has been a factor in diplomacy since the very inception of the institution of diplomacy and the modern nation-state in the seventeenth century. Throughout history states have competed (and at times fought) for control of and access to food and other natural resources, such as water and energy, because they are essential to human survival and inextricably tied to political and economic development. Food and “food security” have always been important concerns of governments, especially for developing countries that have food problems, such as malnutrition, low agricultural productivity, instability of
supply, and food scarcity. Food security is a complicated and increasingly difficult goal to achieve. Although world food output has significantly increased since the end of World War II, poverty, agricultural mismanagement, and population growth in many developing countries undermine prospects for solving the world’s food problems. Indeed food insecurity in developing countries, particularly in Africa, appears to have worsened, highlighting the uneven availability of and access to food and the politicized nature of both food production and distribution and the food aid system.

In general the term food diplomacy refers to the use of a country’s food resources to influence global food markets and to influence international political and economic relations beyond the food market. Using food resources to influence food markets involves goals associated with the functional and structural aspects of the world food economy and the international trade in food, such as increasing the efficiency of food production, meeting minimum levels of food consumption, stabilizing food prices, and managing the disposal and distribution of surpluses. It is this dimension of food diplomacy that deals most explicitly with questions of food security and the policy differences between the major “food exporters” (i.e., the United States, Canada, Australia, the European Union, and Argentina for wheat and coarse grains; China, Pakistan, Thailand, the United States, and Vietnam for rice) and food importers, particularly the poor “food-deficit” countries in the developing world. Using food resources to influence international relationships beyond international food markets involves other foreign policy goals, such as advancing geostrategic interests abroad, increasing economic cooperation or strengthening political relations with another country, and punishing or sanctioning adversaries. This dimension of food diplomacy is much more controversial because it can be at odds with international humanitarian principles and the goal of world food security.

As a practical matter, it is impossible to separate the two dimensions of food diplomacy. There are political and economic consequences of food transfers, as there are for other commodities, such as oil. Even food aid (e.g., the U.S. Food for Peace program) is politicized and is one of the more sensitive points in agricultural trade negotiations between the United States and the European Union in the World Trade Organization’s Doha Round. While the number of instances in which food has been employed as a political instrument of a country’s foreign policy is relatively small, there have been some prominent cases. During the cold war, for example, the United States cancelled 17 million tons of grain sales to the Soviet Union as a form of punishment for the Soviet invasion of Afghanistan and temporarily halted food shipments to Bangladesh because it had traded jute with Cuba. Food has been a key element of efforts by the United States, China, Russia, Japan, and South Korea to convince North Korea to abandon its nuclear weapons program.

FORCES OF PRODUCTION

Forces of production is a term used in political economy that refers to the physical means and techniques of production to which laborers add value and transform capital into products for sale. Forces of production include instruments of production and raw materials, as well as the productive faculties of producing agents manifested by strength, skill, and knowledge. G. A. Cohen (2000, p. 37) argues that instruments of production and raw materials have productive forces, whereas labor power is a productive force.

Distinction must be made between forces of production and the ways they are utilized. Karl Marx wrote: “Powder remains the same whether it is used to wound a man or to dress his wounds” ([1847] 1982, p. 185). It can be argued that in Marx’s view, forces of production are the driving factor in historical development. A new mode of production evolves when there is a conflict between the emerging production forces and the existing social relations. Thus, at a certain stage of development, modern industry becomes incompatible with the social production relations of handicraft (Marx [1867] 1977).

The “correspondence” between forces of production and relations need not be interpreted only as symmetrical, but can be interpreted as implying a priority of one over the other. This is the case made by Cohen (2000), who argues that the distinction between relations of produc-
tion and forces of production is a special case of Marx’s opposition of social to material features of society.

Irrespective of the primacy of forces of production or of social relations, some have insisted that different modes of production may exist simultaneously, which implicitly questions the rigid correspondence of production forces to given social relations. In various ways, feminists have utilized the notion of feudal relations to describe serf-like relations within households in capitalist economies with regards to unpaid domestic work (Benston 1969; Fraad, Resnick, and Wolff 1994).

In Marx’s formulation, people enter into historically and geographically specific social relations that correspond to a given stage in the development of the material forces of production. As Marx puts it, the hand-mill gives society with a feudal lord; the steam-mill—industrial capitalism (Marx [1847] 1982, p. 109). The pairing of forms of technology to forms of social relations implies certain inertia and warranted predictability of historical development, which Lary Hickman calls “future-technological stage determinism” (1990, pp. 142–144). Thorstein Veblen (1906) and most of his followers in the tradition of American institutionalism (evolutionary economics) critique this teleological notion of social change and the idea that there is a final known end to which production process converges.

A notion of forces of production that drive historical development in a teleological manner has ramifications with regards to our understanding of “progress” and “development.” Marx argues: “The country that is more developed industrially only shows, to the less developed, the image of its own future” ([1867] 1977, p. 90). Hickman (1990, pp. 143–144) offers two readings of this statement. First these “iron laws” operate only as long as a society adopts specific forces of production, and this is not necessarily inevitable (“limited technological-stage determinism”). Thus, while there is pairing between forces of production and social forces, there is place for variation. Alternatively, a given society inevitably passes through a given technological stage (“unlimited technological-stage determinism”). Thus, there is a notion of an ideal that ought to be achieved if a society is to master “modern” forces of production and social relations. Such a notion of forces of production brings questions about the opposition between “traditional” and “modern” that is contested by postcolonial critique (Zein-Elabdin 2004).

FORD MOTOR COMPANY

The Ford Motor Company established a system of modern mass production, labor relations, and wage policies that made it one of the most influential corporations of the twentieth century.

While the Ford Motor Company is the enterprise most closely associated with its namesake, Henry Ford, its incorporation in 1903 marked Ford’s third attempt to build an automobile company. Ford began his automotive career with the short-lived Detroit Automobile Company (1898–1900), which was followed by the Henry Ford Company (1901–1902).

Ford manufactured for both domestic and foreign markets. In its first year of operation, it contracted with an overseas distributor to sell cars in Canada and Europe. In 1905 a Canadian plant began producing Ford vehicles for the British Empire.

Ford, unlike its chief rival General Motors, did not adopt a multidivisional structure. Ford and Lincoln (later Lincoln-Mercury), purchased in 1922, remain the only divisions within the auto company. A similarly atavistic quality characterizes Ford’s ownership and management. The Ford family has consistently played a dominant role in ownership or direct managerial control throughout the company’s history. This structure of centralized control is
Ford Motor Company

at odds with the historical trajectory toward managerial capitalism typical of most large-scale twentieth-century American corporations.

Ford engineers did not invent the modern assembly line. The basic concept was adapted from the meatpacking industry, in which animals were transported along a system of overhead pulleys and systematically butchered. Over the years 1910 to 1914 the assembly line evolved from the system of conveyors and gravity slides on which the Model T car was assembled in tightly sequenced stages. Production at the Highland Park plant relied on work rhythms that matched the pace of machines. Rather than using general-purpose tools and machinery, Ford manufactured machines to achieve specific tasks. Individual parts were made to be interchangeable, in order to speed production and reduce the need for skilled craftsmen. Investment in expensive, specialized machinery allowed for the introduction of economies of scale whereby unit costs fall as output rises. Ford produced half a million cars in 1915 and two million cars and trucks in 1923. It diversified into shipbuilding during World War I and aircraft manufacture in 1926. In addition to Europe and the British Empire, the newly industrializing Soviet Union was an important market; by 1927 the majority of tractors in the Soviet Union were Ford-built Fordsons. That same year Ford announced plans to acquire a 3,900-square-mile tract of land in Brazil to use as a rubber plantation to be named Fordlandia.

Integrated mass production was taken even further with the construction of the sprawling Rouge River plant in Dearborn, Michigan, during the 1920s. The Rouge plant inspired the photographer Charles Sheeler, whose pictures of it appeared in the pages of Vanity Fair magazine, and the painter Diego Rivera, who included it in the Detroit Industry murals; both depicted the factory as an icon of modern capitalism.

Along with time studies, Ford used various other strategies to organize work to meet the efficiency standards of plant machinery. In this sense the Ford system represents a refinement and extension of F. W. Taylor's scientific management approach. The resulting work environment was fast-paced and continuous, and workers were hard-pressed to keep up. Turnover rates reached 370 percent in 1913. In 1914, to overcome workers' resistance to machine-paced industrial work, the company inaugurated a radical plan to double hourly wages to five dollars a day. The extra money took the form of profit-sharing. To qualify for the higher wage, workers needed to demonstrate proper behavior at work and at home. Ford Sociological Department investigators inquired about workers' drinking habits, marital strife, criminal records, church-going activities, and other evidence of moral character. In this way Ford Motor exerted social control over its employees off the job, as well as technical control of work efforts on the job.

Ford paid black workers the same wages as similarly qualified white workers. While blacks comprised between 10 and 20 percent of the workforce at Ford, they were overwhelmingly assigned the most dangerous, difficult, and unpleasant jobs, such as those in the foundry. Because their wages were far superior to those obtainable from any alternative sources of employment, black workers, especially young married men, were much less likely to quit these jobs and less willing to embrace unionization.

To expand sales, Ford needed to encourage new segments of the population to buy cars. Higher wages allowed workers to acquire mass-produced goods. The interdependence of mass production and mass consumption came to be characterized as Fordism. The Italian political theorist Antonio Gramsci used the term to describe the combination of social, technological, and political control over workers' lives. It has since been extended to cover all institutions (factories, unions, families, and the state) that help to regulate the accumulation of profit in advanced capitalist economies.

Workers at Ford Motor unionized in 1941, four years after the United Auto Workers gained recognition at General Motors and Chrysler. Unionization at Ford was preceded by a strike at the Rouge plant that resulted in Ford's recruitment of African American strikebreakers, thereby exacerbating racial divisions within the ranks of the working class at Ford. During this same year U.S. manufacturers, following directives from the government's Office of Production Management, shifted to wartime production. Ford announced plans to mass-produce bombers at a new plant in Willow Run, Michigan. The Rouge plant was turned over to the production of aircraft engines and jeeps.

After the death of Henry Ford in 1947 and, earlier, that of his son and heir apparent, Edsel, in 1943, Henry's grandson Henry II headed the company. He transformed the organization by bringing in modern management experts (nicknamed the "Whiz Kids") with little or no experience at Ford. Among these new Ford executives was Robert McNamara, who later served as secretary of defense in the Kennedy and Johnson administrations during the Vietnam War.

The U.S. automobile market after World War II was marked by both consolidation—leading to the dominance of the "Big Three" (GM, Ford, and Chrysler)—and the increasing presence of foreign models. In 1955 Toyota Motors built its first modern Japanese mass-production plant, modeled on Ford's Rouge factory. In 1957 foreign automobile imports to the United States exceeded exports for the first time in over half a century. Ford began to reassert control of its foreign subsidiaries in Canada and
Britain. In 1957 the European Common Market was formed. This spurred Ford to try to build cars for regional rather than national markets (Europe instead of Germany, for instance). In 1967 Ford of Europe was established and in the 1970s it introduced an ultra-subcompact car. From the 1980s through the mid-1990s Ford was the leading car company in Europe. Nevertheless, more aggressive plans to build a world car that would integrate North American and European markets failed to produce success.

As part of this strategy of global integration, Ford completed a series of acquisitions in the 1980s and 1990s that included producers from Japan (Mazda), Europe (Volvo), and Britain (Jaguar, Land Rover, and Aston Martin). Ford recovered from the OPEC oil crisis of the 1970s and the product quality problems of the 1980s by designing the best-selling Taurus along with the increasingly popular Explorer sport utility vehicle. By 1995 Ford's share of the U.S. automobile market stood at 25.6 percent. However, well into the first years of the twenty-first century the company continued to rely on sales of trucks and sport utility vehicles at a time when environmental concerns and dependence on foreign oil were emerging as major concerns for U.S. consumers. Ford CEO William Ford Jr. sought to reorient production toward environmentally friendly hybrid vehicles while continuing to offer traditional gas-powered cars. The Rouge plant was reengineered to incorporate green building technology. As Ford's share of the U.S. market fell below 20 percent during the 2000s, the company embarked on a strategy of planned shrinkage of facilities and workforce in the United States. This mirrored the trend toward shrinking market share and falling sales for each of the Big Three U.S. auto companies.

FOREIGN POLICY

Foreign policy, conceptualized most broadly and simply, is the totality of a state’s external behavior toward other states and nonstate actors (e.g., international organizations and terrorist organizations). Foreign policy involves everything from the most consequential decisions about war and peace to more seemingly mundane issues of tariff levels on imports. Foreign policy encompasses long-term goals and objectives (e.g., the U.S. policy of containing the expansion of Soviet influence during the cold war) as well as discrete decisions and actions (e.g., the Soviet Union’s decision to deploy nuclear weapons in Cuba in 1961).

In the social sciences, foreign policy analysis emerged in the 1960s as a subfield of international relations. Foreign policy analysis represented a conscious attempt to move beyond what were seen as predominantly descriptive, unsystematic, and atheoretical accounts of foreign policy often found in diplomatic histories and policy analyses in opinion journals. The goal was to study the determinants of foreign policy behavior in a more theoretically oriented and empirically rigorous manner. This rigor was reflected in greater attention to data gathering and analysis, the development and testing of theory, and a move away from single country studies to more comparative analyses designed to assess the relative importance of various determinants of foreign policy. In this sense, foreign policy analysis reflected the broader trend of behavioralism in political science and the social sciences more generally in the 1950s and 1960s.

One of the first manifestations of the move to greater rigor in foreign policy analysis was the development of frameworks to help organize both empirical research and theory development. The frameworks that eventually
exerted the greatest impact on how scholars thought about foreign policy and conducted their research involved some version of what came to be known as the levels of analysis. The hope was that the use of such common frameworks would encourage scholars to think more systematically about the sources of foreign policy while making empirical research more cumulative.

LEVELS OF ANALYSIS

As with all social sciences, the study of foreign policy is ultimately about understanding human behavior, whether people are acting alone as individuals or in groups as social collectives. As Valerie Hudson notes, “Understanding how humans perceive and react to the world around them, and how humans shape and are shaped by the world around them, is central to the inquiry of all social scientists, including those in IR [i.e., international relations]” (Hudson 2005, p. 1). Though foreign policy analysis can be differentiated from other social sciences in terms of the actor and behavior in question, many of the basic insights for understanding any type of human behavior are relevant and have been adapted for the study of foreign policy.

Generally speaking, there are two types of explanations for the behavior of any social actor. We can loosely refer to these as dispositional and situational. Dispositional explanations portray an actor’s behavior as the result of some feature or characteristic of the actor itself: An actor behaves in a certain way because something about the actor predisposed it to behave in a particular fashion. Situational explanations focus on external forces that shape an actor’s behavior regardless of its unique characteristics: Something in the actor’s environment led it to behave in a certain way. In all but the most extreme instances of course, social scientists recognize that any actor’s behavior results from some combination of dispositional and situational forces. Thus the goal of most social scientific inquiry is to determine the relative importance of dispositional/internal and situational/external forces in shaping an actor’s behavior.

Kenneth Waltz (1959) was among the first to introduce a similar scheme into international relations. Focusing on theories of war, not foreign policy per se, he drew a distinction between individual-, national-, and international-level explanations of state behavior. Numerous versions of the basic scheme incorporating further refinements and distinctions within the different levels have been developed and applied since its first appearance. The most influential of these was presented in 1966 by James Rosenau in his call for the development of “theories and pre-theories” of foreign policy.

Several levels of analysis highlighted by Rosenau are common to virtually all such frameworks. The individual or idiosyncratic level focuses on the decision makers themselves and draws heavily on research and theory from social and cognitive psychology. Research at this level has examined the impact of personality traits, beliefs/perceptions, and cognitive processes. The societal level deals with the impact of general national attributes, such as a state’s economic system, regime type, level of development, public opinion, or political culture. The governmental level emphasizes the institutions and dynamics of decision-making processes, particularly bureaucratic competition and organizational dynamics. The international level stresses the general impact of the anarchic and competitive nature of an anarchic international system, a state’s position in the overall distribution of power, and factors such as geography. Two things are apparent from the levels-of-analysis frameworks and determinants of foreign policy specified within each level: First, any explanation of a state’s foreign policy will certainly incorporate elements from multiple, if not all, levels; second, the study of foreign policy is by its very nature multidisciplinary, drawing on insights from a wide array of social sciences. In this respect, once again, foreign policy is probably no different than most other social phenomena.

MODELS OF FOREIGN POLICY

Graham Allison (1969, 1971), in his seminal article and book on decision-making during the Cuban missile crisis, claimed that observers often analyze and explain foreign policy through the lens of a rational actor model. Either implicitly or explicitly, analysts portray states as unitary actors possessing a coherent set of ranked national goals and objectives. According to this model, states confronted with international circumstances that require action will craft, evaluate, select, and implement policy options that maximize these goals and objectives. This rational actor model is often applied in reverse to understand a state’s foreign policy and determine what its goals and objectives might be. If a nation deploys a certain weapons system or decides to use force, for example, observers assume that this policy was chosen in order to maximize its goals and objectives. As Allison explains, “This paradigm leads analysts to rely on the following pattern of inference: if a nation performed a particular action, the nation must have ends toward which the action constituted an optimal means” (Allison 1969, p. 694). A rational actor model views foreign policy as an intellectual or analytical, as opposed to political, process. Though a rational model is often applied implicitly, some international relations adopt it explicitly, even though they realize that it is usually not an empirically accurate portrait of how foreign policy decisions are made. In their view, such unrealistic simplifications of reality are theoretically useful and necessary even if they are descriptively inaccurate. Allison, among others, argued that the routine application of the
rational actor obscures a genuine understanding of foreign policy: The “black box” of the state needs to be opened and unrealistic assumptions abandoned or modified if we want to understand and explain state behavior. In fact one of the underlying goals of levels-of-analysis frameworks and their inclusion of domestic and individual variables is to direct attention to the internal workings of the state and decision-making processes.

With the goal of better understanding foreign policy, Allison presented two other models that offered better pictures of how foreign policy is actually made: the bureaucratic politics model and the organizational process model. In the bureaucratic model, the state is not seen as a unitary rational actor but rather as a collection of actors representing governmental organizations with different perspectives, goals, and objectives. There is no single, coherent, and ranked set of national goals and objectives. Policy is the result of a political process, not an analytical process. In this model, “the decisions and actions of governments are essentially intra-national political outcomes” (Allison 1969, p. 708). Decision makers are seen as reflecting the interests and perspectives of the government bureaucracies they represent, a tendency embodied in the cliché that where one stands (on any given issues) depends on where one sits (within the government). A state’s behavior should be seen as reflecting the relative power of the players in the process, not as something designed to maximize a well-defined national interest. Under other circumstances, it might make more sense to understand foreign policy through the lens of an organizational process model. This model assumes that states are large organizations that seldom reevaluate policy from scratch and consider the full range of options when action is required. The crafting, evaluation, choice, and implementation of policy options are often determined by such factors as precedent and the standard operating procedures and routines usually found in any large organization.

Allison did not claim that the bureaucratic and organizational models were always more accurate than the rational actor model. Nor did he suggest a complete rejection of the rational actor model. In laying out the models and applying them to the Cuban missile crisis, Allison was attempting to make two points. First, there are some, perhaps many, circumstances in which foreign policy decisions may be the result of different decision-making processes and dynamics. Second, the alternative models are useful for highlighting and illustrating the real world constraints and forces that limit the applicability of rational models to understand foreign policy (or policy in any area for that matter).

EXPLAINING FOREIGN POLICY
One problem with levels-of-analysis frameworks is that they often result in a seemingly endless laundry list of variables that influence foreign policy. Those seeking to explain a state’s behavior can easily become overwhelmed by the proliferation of determinants at each level. It is easy for the analyst to drown in a sea of details and determinants. Analysts need to find some way to include more without becoming overwhelmed. To deal with this problem, it is useful to emphasize that foreign policy can encompass everything from general policy orientations that persist over long periods to discrete decisions. There is a need for some precision about exactly what one wants to explain. If an analyst wants to explain why Great Britain pursued a policy of naval supremacy throughout most of the eighteenth and nineteenth centuries, this is very different from trying to explain a particular decision about the use of force. In thinking about the determinants of broad policy orientations such as Britain’s policy of naval supremacy, it would make little sense to look to the personality traits of British prime ministers. Behaviors and policies pursued over long periods are more likely to be the result of similarly enduring determinants such as geography and culture. On the other hand, if one is trying to explain a specific decision, such as Britain’s military response to the Argentinean seizure of the Falkland Islands in 1983, it might very well make sense to focus on leader traits (Prime Minister Margaret Thatcher in this case). Foreign policy analysis requires clarity not only in terms of the determinants of policy but also what is to be explained. In this way, one thinks about which determinants are likely to “match up” with the level of policy one is seeking to explain.

Similarly analysts sometimes worry about the proliferation of models. The critical point is to remember that there is no reason to assume that any one model is generally applicable. The description of various decision-making models merely highlights the fact that not all decisions are the result of the same process. The process itself is likely to vary with the nature and importance of the issue at hand, the amount of time decision makers have to act, and whether the problem is new or familiar. Critical issues of war and peace and the use of force, for example, are almost always decided at the highest levels, not within the confines of bureaucracies and organizations. As a result these decisions may more closely resemble the rational actor model. If the problem requiring a decision is novel or unfamiliar, there are unlikely to be preexisting, organizational, standard operation procedures that can be applied. If decision makers have little time to make a decision, they may be unable to craft and evaluate a wide range of new policy options and may thus choose to implement preexisting plans or routines. If the policy has important consequences for the allocation of resources, the influence of bureaucratic politics may be greater. Analysts need to think about the issues and conditions that are most conducive to different decision-making processes.
The development of levels-of-analysis frameworks and alternative decision-making models were both attempts to move analysts away from the tendency to view foreign policy as a rational and strategic response to external events. As Waltz, frequently criticized for treating states as unitary, rational actors, admits, “foreign-policy behavior can be explained only by a conjunction of external and internal conditions” (Waltz 1993, p. 79). In most political science departments, foreign policy is treated as a subfield of international relations. There are good reasons for this, given that the focus is on the external behavior of states. But one could make an equally compelling case that it should be viewed as a subfield of public policy, since there is no compelling reason to believe that foreign policy is free of all the same influences that shape policy in other areas. Foreign policy is, after all, foreign policy.

FORESIGHT, PERFECT
A term of everyday use, foresight, when qualified by perfect, is elevated to a concept of signal importance, certainly for modern economic theory with its proclivity to fixed points, but perhaps also for social sciences more generally. This entry attempts a brief overview.

In his analysis of investment decisions in chapter 12 of The General Theory of Employment, Interest, and Money (1936), John Maynard Keynes (1883–1946) draws attention partly to “existing facts, known more or less for certain” and partly to “future events, forecasted with more or less confidence” (Keynes 1936, p. 147).

The state of long-term expectation does not solely depend on the most probable forecast that we can make. It also depends on the confidence with which we make this forecast—on how highly we rate the likelihood of our best forecast turning out quite wrong…. The state of confidence … is a matter to which practical men always pay the closest and most anxious attention. (p. 148)

Keynes (p. 152) emphasizes that our projections into the future, as well as our assumption that the “existing market valuation, however arrived at, is uniquely correct in relation to our existing knowledge of the facts” are based on a convention whose essence lies in the assumption of stationarity.

In practice we have tacitly agreed, as a rule, to fall back on what is, in truth, a convention. The conventional method of calculation will be compatible with a considerable measure of continuity and stability in our affairs, so long as we can rely on the maintenance of the convention. But it is not surprising that a convention, in an absolute view of things so arbitrary, should have its weak points. (p. 152)

These points are collected under four headings, but with the proviso that “philosophically speaking, [market evaluations] cannot be uniquely correct since our existing knowledge does not provide a sufficient basis for a calculated mathematical expectation” (p. 152).

Undoubtedly familiar with the writings of French mathematician and economist Antoine Augustin Cournot (1801–1877), Keynes does not formulate or work with the notions of rational expectations equilibrium or self-filling expectations. (See Merton [1936, 1948] for his historical take on the idea encapsulated in these phrases.) In a Cournot-Nash equilibrium, each individual action, taken on the basis of a judgment about the facts of the situation, a judgment that not only takes the actions and judgments of others into account in ascertaining the facts of the situation as they find and judge it, but also allows their judgments, and consequent potential actions, to
incorporate all that it itself takes into account, ends up by generating precisely the shape of the situation it initially took into account. In Keynes's General Theory, the word foresight is used nine times, perfect appears four times, and imperfect five times, but the two adjectives are never used to qualify the noun. Keynes refers to a correct state of expectation and correct foresight, the latter twice, but in as much a negative, possibly ironic, light as in a positive one. Hindsight, perfect or imperfect, is never employed to subdue and discipline history, as the assumption of perfect foresight is now sometimes used to discipline data and neutralize the future in theoretical thinking current in macroeconomics and associated with Brock (1972, 1974), Lucas, Lucas and Prescott (1971) and their followers. (For issues relating to perception and individual observability, see Chakrabarti and Khan, 1991.)

Nevertheless, Keynes's chapter 12 is impressive in how it draws on and anticipates the vernacular of modern game theory and finance. (For epistemological concerns stemming from Nash (1951), see Aumann and Brandenburger (1995) and Khan (1990, section 2.)) Referring to investment as a “battle of wits,” and using metaphors for games that are played with “zest and enjoyment” even though the players know what they entail and their sorry end, Keynes introduces game-players and player-types: uninformed versus informed investors “as gulls among the public to feed the maws of the professionals” (Keynes 1936, p. 155), and speculators versus enterprisers. He emphasizes “animal spirits—a spontaneous urge to action rather than inaction [as opposed to an] outcome of a weighted average of quantitative benefits multiplied by quantitative probabilities” (p. 161), a maximization of von Neumann-Morgenstern expected utilities, and flatly denies that the “basis for making such calculations” exists. Anticipating David Lewis (1969) and Robert Aumann (1976), but stopping short of them and of infinite regress (see Parikh and Krasucki (1990) and their references to the work of Geanakoplos-Polemarchakis, Cave and Bacarach), Keynes writes:

We have reached the third degree where we devote our intelligences to anticipating what average opinion expects the average opinion to be. And there are some I believe who practice the fourth, fifth and higher degrees. (1936, p. 156)

Once the investment decision is reviewed as part of an anonymous multiplicity of decentralized decisions taken by producers and consumers, independent of each other except for their dependence on the price system, as in the Arrow-Debreu-McKenzie theory, the facts of the situation refer only to the price system. (Debreu (1959), Nikaido (1968), Arrow and Hahn (1971) and McKenzie (2002) represent the loci classicus of a theory to which many others have made fundamental contributions. See Khan (2004) for a reading of Debreu through the eyes of Keynes and his Cambridge predecessors and successors, including Frank Hahn.) If however, there are facts that are not, perhaps cannot be, “priced out,” and agents have differential informational access to these facts but not to each other, then the price system can be used by each to gauge the information and beliefs of the others, and to refine their decisions accordingly. (Hayek (1948) is now a classic reference on differential information.) Such a context is particularly amenable to attempts at equilibrium theorizing. James Jordan and Roy Radner refer to agents’ individual models, endow these models with a measure of rationality, and introduce the 1982 Journal of Economic Theory symposium with these words:

In a market for commodities whose future utility is uncertain, the equilibrium prices will reflect the information and beliefs that the traders bring to the market, as well as their tastes and endowments. The term rational expectations equilibrium is applied to a model of market equilibrium that takes account of this potential informational feedback. (Jordan and Radner 1982, p. 201)

A situation in which agents have identical information regarding an uncertain environment, Keynes’s convention becomes the theoretical reality, and an equilibrium that features a “correct” price-expectation function can be formulated. Under the heading of a perfect foresight approach, Radner (1982) refers to this as Muth’s (1961) idea of rational expectations, and distinguishes it from the one originally formulated, in 1967 and subsequently, to deal with differential information (see also Jordan and Radner 1982, para. 6, and Sent 1998).

Margaret Bray (1987) focuses on the perfect foresight hypothesis in what Radner describes as Muth’s sense. In addition to following Radner in designating John Hicks (1939) as another precursor, Bray also discusses the early work of Nicholas Kaldor (1934). Her conclusion that “there is little to be gained in realism by exchanging the myth of complete markets for the fantasy of perfect foresight” (Bray 1987, p. 834) surely stands twenty years later; I leave it to the reader, and to a more detailed subsequent investigation, to determine how much the hypothesis has gained for the theory and for the understanding of competitive markets, themselves nothing if not intertemporal. (See Aumann (1998) and his references for issues centered on temporality.)

**FORMAN, JAMES 1928–2005**

In his “Letter to My Sisters and Brothers,” which opens his book *The Making of Black Revolutionaries*, James Forman writes, “We are not born revolutionary. Revolutionaries are forged through constant struggle and the study of revolutionary ideas and experiences.” This statement captures a central aspect of the social and political thought of the civil rights leader. Throughout his life, Forman constantly emphasized the essential relationship between thought and action in the struggle for social and political change. In so doing, he left an indelible mark on the history of African American political thought and protest movements.

Born on October 4, 1928, in Chicago, Illinois, James Forman spent the first years of his life on his grandmother’s farm in Benton County, Mississippi. At the age of six he went to live with his mother and stepfather in a four-room apartment on the South Side of Chicago. He attended grammar school at St. Anselm’s Catholic School.
and then transferred to Betsy Ross Grammar School. During his grammar school years Forman sold the Chicago Defender, an influential African American newspaper that proved to be a catalyst in developing his political conscience. Graduating with honors from Englewood High School in 1947, James spent one semester at Wilson Junior College before volunteering for service in the United States Air Force. While stationed in California, he took classes at the University of Southern California. Upon returning to Chicago in 1954, Forman enrolled in Roosevelt University, where he took an active role in student politics. He graduated with honors in 1957 and, with the assistance of a professor, St. Clair Drake, began graduate school in the Government Department and the African Research and Studies Program at Boston University.

With the advent of a burgeoning civil rights movement, Forman decided to leave graduate school and take an active role in the struggle for racial justice. He covered the integration of the Little Rock public schools for the Chicago Defender, and while teaching at Paul Cornell Elementary School in Chicago, he took an active role in the protest struggles of African American sharecroppers in Tennessee. But it was through his work with the Student Nonviolent Coordinating Committee (SNCC)—as executive secretary and director of international affairs—that Forman was able to make a significant contribution to the civil rights revolution. Forman's organizational prowess, along with his deep commitment to forging effective ideological positions for SNCC, contributed to the organization's political effectiveness. Although he often disagreed with the strategies, tactics, and philosophies of other SNCC leaders, such as Bob Moses, as well as other civil rights organizations, Forman was a central figure in transforming SNCC into one of the “Big Five” civil rights organizations—the others being the Congress of Racial Equality (CORE), the National Association for the Advancement of Colored People (NAACP), the NAACP Legal Defense Fund (LDF), and the Southern Christian Leadership Conference (SCLC).

As SNCC experienced tremendous ideological tensions and fractures, Forman withdrew from active participation in the organization in 1968. He briefly affiliated with the League of Revolutionary Black Workers, a labor organization that worked with African American autoworkers in Michigan. In 1969, Forman formulated his “Black Manifesto” at the National Black Economic Development Conference. The Manifesto became widely known after he interrupted the May 4, 1969, service at New York’s Riverside Church to read his formal call for reparations for African Americans. Over time, Forman’s political thought evolved to more fully take into account thinkers and movements from the Third World. He also developed a more pointed critique of capitalist political economy. Forman eventually earned his Master’s degree in African and African American history from Cornell University and his PhD in political history from the Union of Experimental Colleges and Universities. In 1984, he published a revised version of his graduate school research as Self-Determination and the African American People. He continued to be active in a number of national and international political movements, including running an unsuccessful campaign in 1990 to become the “shadow” U.S. senator from Washington, D.C. (The two “shadow senators” are nonvoting representatives who lobby Congress on behalf of the District of Columbia.) James Forman died on January 10, 2005, after a battle with colon cancer.

FORMATION, RACIAL

Introduced in 1986 by Howard Winant and Michael Omi, the theory of racial formation has extensively influenced the field of racial and ethnic relations. Racial formation theory extends the general sociological principle of race being a socially constructed concept that is contested and undergoes changes over time. Primarily an analysis of how U.S. society has been re-racializing since the 1960s through a number of racial projects, the theory discusses the transformation of racial categories largely by efforts in the political arena and the ways in which racial meanings affect this process.

Omi and Winant define racial formation as “the sociohistorical process by which racial categories are created, inhabited, transformed, and destroyed” (1994, p. 55). They argue that this process of racialization is situated between structure and representation, whereby, at certain points in history, racial meaning is extended to a racial relationship, social practice, or group. Racial ideology is constructed and reconstructed from preexisting conceptual elements and emerges from the struggles of competing political projects and ideas seeking to articulate
similar elements differently. Additionally, Omi and Winant argue that race is an organizing principle not just at the societal (macro) level, but also at the individual (micro) level, shaping the identities of individuals and affecting all areas of social life. However, they do give substantial emphasis in their analysis to the macro level, arguing that racial conflict occurs primarily at the level of the state. In their estimation, the process of racial formation takes place in two steps: through racial projects and the evolution of hegemony.

RACIAL PROJECTS
Omi and Winant (1994) argue that society is suffused with racial projects, which form the “heart” of the racial formation process. They define a racial project as “simultaneously an interpretation, representation, or explanation of racial dynamics, and an effort to reorganize and redistribute resources along particular racial lines” (1994, p. 56). Racial projects are the link between structure and ideology, in that they mediate between the discursive ways race is identified and signified on one hand, and the institutional forms in which it is routinized on the other. Racial projects give us new ways of reasoning about race, new plans for action, and often new language and discourse with which to talk about race and possibly even mask racist ideas.

Through historical analysis, Omi and Winant assert that the most successful racial projects since the 1960s (largely carried out by neconervative members of the ruling class) have furthered the notion that liberal racial policies gone wrong are to blame for many of society’s problems. For example, affirmative action programs created by whites to modestly address some extreme racial inequities have been effectively reframed as “reverse discrimination,” harmful to white Americans’ life chances, and even detrimental to beneficiaries of color on a psychological level. This racial project was one of several competing projects, but eventually prevailed in the political and social arenas.

CONTRIBUTION AND CRITICISM
The theory of racial formation had a major impact on the study of racial and ethnic relations and is incorporated into most critical race scholarship. Little prior theory, in addition to much current mainstream research, gives attention to the role of government in creating racial-ethnic groups and, instead, a great deal of scholarship attempts to subsume contemporary racial issues underneath matters of ethnicity, nationality, or class (e.g., Wilson 1980). However, while Omi and Winant’s theory gives important insight into racial formation as a free-standing social process, critical race scholars give some noteworthy critique.

Some race theorists argue that Omi and Winant give ideological processes excessive emphasis, and little attention is devoted to how racial orders are structured (Bonilla-Silva 2001; Feagin 2006). Specifically, the racial formation theory does not aid understanding of the ways in which the ideological formation of race has been buttressed by extensive generation of wealth and assets for white Americans (Feagin 2006). Thus, Omi and Winant attend well to the symbolic and less well to the structural.

Similarly, because Omi and Winant do not present racial groups as collectivities who contest their positioning in the racial hierarchy, their analysis casts little light on why people fight over racial matters and either accept or challenge racial projects (Bonilla-Silva 2001). Omi and Winant also claim that the most recent rearticulation of the racial ideology has been carried out by certain right-wing members of the dominant class, but this analysis neglects a systemic understanding of the process (Bonilla-Silva 2001). Nevertheless, racial formation theory provides subsequent scholars with a solid reference point for the racial theories of the future.

FORMATION, SOCIAL
Social formation is a Marxist concept referring to the concrete, historical articulation between the capitalist mode of production, persisting precapitalist modes of production, and the institutional context of the economy. The theory of the capitalist mode of production—its elements, functioning at the enterprise level and the level of market relations among enterprises (e.g., processes of competition, concentration, and centralization), and its contradictions, tendencies, and laws of motion—can be found in
Karl Marx's *Capital* ([1867] 1967). The capitalist mode of production as such is an abstraction, accessible to research only through social formations; that is, through its concrete, historically specific manifestations in nation states, regions within nations (e.g., the South), or regions encompassing nations (e.g., the European Union). Though Marx (1818–1883) did not define this concept, its meaning and significance can be inferred from his work, particularly from this statement:

> The specific economic form, in which unpaid surplus-labor is pumped out of direct producers, determines the relationship of rulers and ruled ... and, in turn, reacts upon it as a determining element. Upon this, however, is founded the entire foundation of the economic community which grows out of the production relations themselves, thereby simultaneously its specific political form. It is always the direct relationship between the owners of the conditions of production to the direct producers.... which reveals the innermost secret, the hidden basis of the entire social structure, and ... the corresponding specific form of the state. This does not prevent the same economic basis—the same from the standpoint of its main conditions—due to innumerable different empirical circumstances, natural environment, racial relations, external historical influences, etc., from showing infinite variations and gradations in appearance, which can be ascertained only by analysis of the empirically given circumstances. (Marx [1867] 1967, vol. 3, pp. 791–792)

Marx postulates here a necessary, dialectical interrelation between relations of exploitation and political relations, between economic and social systems, a point previously made as follows: “The totality of these relations of production constitutes the economic structure of society, the real foundation, on which arises a legal and political superstructure and to which correspond definite forms of social consciousness” (Marx [1859] 1970, p. 20). The historical specificity of the relations of production is crucial for understanding the social formation in its universality (i.e., as a capitalist social formation) and in its particularity because, empirically, “the same economic basis” (i.e., the capitalist mode of production) will show “infinite variations” due to a social formation’s unique characteristics among which, the presence and persistence of precapitalist modes of production are of key importance. This is why the study of social formations entails the investigation of the articulation of modes of production; that is, the specific ways in which the capitalist mode of production affects precapitalist modes of production, altering them, modifying them, and even destroying them (Wolpe 1980, p. 2).

**RECENT INTERPRETATIONS**

The relationship between the capitalist mode of production, social formations, and social change has been interpreted in determinist and dialectical ways. Literal, atheoretical readings of the work of Marx and Friedrich Engels (1820–1895) reduce their views to technological and economic determinism, a result produced also by sophisticated but undialectical readings (e.g., Cohen 1978) that ignore the dialectical nature of Marx’s thought. Marxist concepts are essentially material and social; for example, a machine, in itself, is a physical object that becomes a means of production or a productive force when it enters the production process in the context of historically specific relations of production. Changes in the forces of production occur, it follows, always in the context of political struggles. Cohen, on the other hand, attributes to the productive forces a primary, determinant role in historical change, and he radically divides the social (e.g., relations of production) from the material or extrasocial (i.e., nature, humans, forces of production). Cohen’s undialectical materialism and determinism has to rely, unavoidably, upon transhistorical sources of change: a universal tendency of the productive forces to develop and a “somewhat rational” human nature capable of coping with scarcity (Cohen 1978, pp. 132–160). From this standpoint, then, historical changes are the effect of changes in the forces of production, undialectically understood as mere technological change. Class struggles play no role in historical change for political actors are reduced to rationally adapting to the effects of changing circumstances.

A determinist understanding of Marx would lead social scientists to expect that the penetration of the capitalist mode of production in social formations where precapitalist modes of production are widespread would soon produce qualitative changes in their economic system (e.g., modification or destruction of the precapitalist modes of production) and their superstructure (e.g., culture, legal, and political institutions). Determinist perspectives, however, underestimate the resilience of the noneconomic characteristics of social formations and the extent to which production is a thoroughly social activity that requires social and cultural conditions of possibility that cannot be instituted by decree. Despite appearances, for example, the drastic economic changes introduced in Russia after 1917 and in Eastern Europe after World War II (1939–1945) were, to some extent, superficial, for those countries quickly reverted to capitalism. There are many complex economic and political reasons why revolutionary change did not produce deep and qualitative superstructural changes, but reliance on the determinant and automatic effects of changing the mode of production must have contributed in important ways.
The literature on social formations subject to the penetration of the capitalist mode of production through gradual, nonrevolutionary processes indicates that forms of articulation between the capitalist mode of production and precapitalist modes of production cannot be logically deduced from Marx's theory of the capitalist mode of production. The notion of articulation refers to "the relationship between the reproduction of the capitalist economy on the one hand and the reproduction of productive units organized according to pre-capitalist relations and forces of production on the other" (Wolpe 1980, p. 41). How these processes actually interact varies a great deal from one social formation to another, thus leading to the construction of conflicting perspectives about the nature of social formations: (1) Social formations lack a necessary structure; one mode of production may dominate or several modes of production may be articulated with or without one dominant mode; (2) A social formation's necessary structure may be formed by a dominant mode of production and its conditions of existence, which might include elements of precapitalist modes of production, or it may simply be the effect of the articulation of any number of modes and their respective conditions of existence; (3) Given a dominant mode (e.g., the capitalist mode of production) in any social formation, all other modes will be subordinate to its structures and processes so that they are reduced to mere "forms of existence" of the dominant mode (Wolpe 1980, p. 34).

These and other perspectives entail different implications depending on whether the mode of production is defined in a restricted sense, as a combination of relations and forces of production, or in an extended sense, encompassing linkages among enterprises as well as other economic and political/cultural elements constitutive of the mode of production and conducive to its reproduction over time (e.g., distribution, circulation, exchange, the state) (Wolpe 1980, p. 40; Marx [1859] 1970, pp. 188–199). Because modes of articulation are unique to specific social formations (e.g., in South Africa, racial ideology reproduced and sustained capitalist relations of production [Wolpe 1980, p. 317]; in Peru, agrarian reform contributed to the proletarianization of Indian communities [Bradby 1980, p. 120]), it could be erroneously concluded that social formation and articulation are useless concepts, for their use in research is unlikely to yield testable empirical generalizations.

These concepts are exceedingly important, for they contribute to the adjudication of an important issue in Marxist theory: the extent to which Marx is or is not an economic determinist. The historical and empirical variability in the conditions of reproduction of the capitalist mode of production that is documented through research in social formations and modes of articulation demonstrates the nondeterminist nature of Marx's theories. While the structure, processes, contradictions, and tendencies of the capitalist mode of production remain the same, thus constituting the "innermost secret" of the economic and political structures in social formations where the capitalist mode of production is dominant, the historical conditions for the reproduction of the capitalist mode of production vary historically and cross-culturally in the terrain of social formations, where political struggles carried under a variety of banners (class, race, religion, and nationalism) shape the different and specialized outcomes of capitalism’s never-ending expansionary tendencies.

Dialectically considered, social formations are the unity between the universal (the capitalist mode of production) and the particular, the concrete conditions within which the capitalist mode of production operates. The concept of social formation, unlike the abstract non-Marxist concept of "society," opens up the possibility of a realistic and historical understanding of social reality, based not on inferences from transhistorical tendencies, functional prerequisites, or concepts of human nature, but upon the historical specificity of the social formations within which capitalism operates.

FORMULAS

Although most social science research concerns characteristics of people, groups, organizations, and situations for which there is no inherent metric or measure, virtually all such research involves quantifying these characteristics. The
data that result from this quantification are manipulated, analyzed, and interpreted using mathematical formulas. Formulas also are used by social scientists to describe or model behavior, particularly interpersonal behavior, using mathematical operations and principles. In some social science research literatures, such formulas are the principle means by which behavior is described and predicted.

William James, in his *Principles of Psychology* (1890), offered one of the earliest examples of a description of an aspect of human social experience in mathematical terms. James suggested that self-esteem is a function of the ratio of people’s successes to their “pretensions”:

$$\text{Self-Esteem} = \frac{\text{successes}}{\text{pretensions}}$$

In other words, a person’s self-esteem depends on the degree to which they are meeting their own expectations. Inspired by James’s work, psychologists a century later posited more complex formulas in which self-esteem is a measure of the sum of people’s performances in various domains, weighted by the importance they ascribe to those domains.

An area of social science in which mathematical formulas have been particularly influential is interpersonal relations. Virtually all of these formulas derive in part from social exchange models of interpersonal behavior. The seminal social exchange account of interpersonal relations was proffered by J. Stacy Adams in 1963. Adams’s specific concern was the degree to which individuals feel as if they are treated in a just and fair manner by their employers. According to Adams, perceptions of just and fair treatment stem from perceptions of equity, which can be modeled using the following formula:

$$\text{Equity} = \frac{\text{inputs}}{\text{outputs}}$$

Inputs are what the employee puts into the job (e.g., effort, loyalty), and outputs are what the employee gets in return (e.g., salary, job security). As this ratio departs from 1.0, particularly in the direction of inputs exceeding outputs, perceptions of fairness, as well as motivation, decline.

An important addition to this simple model is an accounting for the role of comparisons in such judgments. For instance, the equity ratio might be expanded to:

$$\text{Equity} = \frac{\text{inputs}_{\text{other}}}{\text{outputs}_{\text{other}}} - \frac{\text{inputs}_{\text{self}}}{\text{outputs}_{\text{self}}}$$

In this case, “other” could denote another person (e.g., a coworker) or another opportunity (e.g., a position with another employer). The addition of comparisons yields a model that can account for the fact that individuals sometimes remain in relationships despite inputs that exceed outputs, or that they leave relationships that are providing outputs in excess of inputs.

Other models inspired by the social exchange perspective use formulas as a basis for defining and predicting relationship outcomes. For instance, Caryl Rusbult’s investment model defines relationship satisfaction using the following formula:

$$\text{Satisfaction} = (\text{rewards} - \text{costs}) - \text{comparison level}$$

This formula specifies that people experience satisfaction in relationships when the difference between rewards and costs in the relationship exceeds expectations. Satisfaction, defined in this way, is a term in the formula for defining commitment to the relationship:

$$\text{Commitment} = \text{Satisfaction} - \text{alternatives} + \text{investments}$$

“Alternatives” corresponds to the perceived degree of satisfaction the individual could expect to experience in other relationships, and “investments” correspond to the accrued costs of staying in the relationship (e.g., opportunities not pursued in order to preserve the relationship). These formulas define relationship outcomes and suggest means by which they can be predicted and influenced, illustrating the strategic use of formulas in social science research.

Other theoretical models in the social sciences specify formulas for which specific values of terms are predicted. An instance of such a use of mathematical formulas is Bibb Latané’s social impact theory. According to this theory, the influence of other people on an individual can be specified in terms of three factors: (1) strength, or how important the individuals are; (2) immediacy, or how close in space and time the individuals are; (3) number, or how many people there are. Social influence, or impact, is a product of these factors, so that:

$$\text{Impact} = \text{strength}^i \times \text{immediacy}^j \times \text{number}^k$$

For example, the model predicts that performance anxiety will increase as the number of individuals watching, their importance to the performer, and their proximity to the performer increases. An important feature of this model is the assumption that the influence of these factors is not linear (i.e., the exponents fall between 0 and 1). Take for instance, the number factor. The model specifies that, holding strength and immediacy constant, the addition of one more person in the situation has less influence if a large number of people are already present. Likewise, the addition of one more person in the situation has more influence if a small number of people are already present. Thus, associated with each factor is an exponent that describes in mathematical terms the relation between that factor and its impact.

Even in social science research for which concepts are not framed in mathematical terms, mathematical formulas are important, because the data generated by social science research is virtually always subjected to statistical analysis. The most prevalent use of formulas in this context is for the construction of test statistics. Test statistics,
such as $t$, $F$, and $\chi^2$, are used in hypothesis testing as a means of evaluating the likelihood that an observed pattern of results is attributable to chance. This likelihood is reflected in the $p$-values that accompany observed values of test statistics, with values lower than .05 indicating, by convention, statistical significance.

A related use of formulas is for the computation of effect sizes, which are means of indexing the practical, as opposed to statistical, significance of a research finding. A frequently used effect size, $d$, is attributable to the American psychological researcher Jacob Cohen. The formula for computing $d$ is:

$$d = \frac{M_1 - M_2}{\sigma}$$

Here, $M_1$ and $M_2$ are means on some outcome for two groups and $\sigma$ is a standard deviation, either for one of the groups or for a “pooled” standard deviation. The resultant value is the difference between the two groups in standard deviation units, which is interpreted with reference to criteria for small, medium, and large effects, as described by Cohen. Other effect sizes can be generated using formulas specific to the statistical model used to analyze the data.

Mathematical reasoning is a routine activity in quantitative social science research. At the most fundamental level, mathematical formulas are, in some instances, used to define and predict variables. In all cases, mathematical formulas are used to construct test statistics required for hypothesis testing. Increasingly, these test statistics are accompanied by effect sizes, which make use of output from statistical analyses to construct indexes of practical significance. For these reasons, social scientists routinely use mathematical reasoning in their work.

**FORWARD AND FUTURES MARKETS**

Futures markets and forward markets trade contracts that determine a current price for a commodity transaction designated to take place at a later date. Despite being fundamental to financial and commodity trading, there is some confusion over the precise definition of futures and forward contracts. While common usage sometimes defines futures and forwards as synonyms, a futures contract is a specialized form of forward contract that is standardized and traded on a futures exchange. As such, a technical distinction is required between futures markets and forwards markets. Some forward contracts, such as those traded on the London Metals Exchange, have many features of futures contracts. Other types of forward contracts are more complicated, such as the forward contracting provisions embedded in long-term oil delivery contracts. While it is tempting to claim that futures contracts represent an evolution of forward trading, much twenty-first-century progress in contract design has come in over-the-counter (OTC) trading, the primary venue for many types of forward contracting.

**HISTORY OF FORWARD AND FUTURES CONTRACTS**

The history of forward contracts can be traced back to ancient times. Due to the difficulties of transport and communication, trading based on samples was common and some form of forward contracting was essential. The contracting process usually involved only the producers and consumers of the goods being traded. During the sixteenth century, liquidity of forward markets was substantially increased by the emergence of the Antwerp bourse. By the mid-seventeenth century, forward markets had developed to where the Amsterdam bourse featured both forward and option contracts for commodities, such as wheat and herring, and for foreign stocks and shares. The beginning of trade in futures contracts is usually traced to mid-nineteenth-century Chicago, where the Board of Trade—founded in 1848—transacted the first “time contract” in 1851. The grain trade of that era typically involved merchants at various points along major waterways purchasing grain from farmers which was then held in storage, often from fall or winter into spring. In order to avoid the risk of price fluctuation and to satisfy bankers, merchants started going to Chicago to transact contracts for future, spring delivery of grain. The contracts set a price for delivery of a standardized grade at a later delivery date. While these early contracts were similar to modern futures contracts, some terms and conditions of these time contracts were specific to the original parties to the transaction, as with a forward contract.
THE FUTURES CONTRACT AND
THE FUTURES EXCHANGE

A significant difference between futures and forward contracts arises because futures contracts are legally required to be traded on futures exchanges while forwards are usually created by individual parties operating in the decentralized OTC markets. Because a futures contract is transacted on an exchange, the traders originating the contract use the exchange clearinghouse as the counter-party to their trade. While both a short trader (seller) and long trader (buyer) are required to create a futures contract, both traders execute the trade with the clearinghouse as the direct counter-party. This allows a futures contract to be created without the problems associated with forward contracting, which typically depends on the creditworthiness of the counter-party. By design, futures contracts are readily transferable via the trading mechanisms provided by the exchange. Because forward contracts depend on the performance of the two original parties to the contract, these contracts are often difficult to transfer. One practical implication of this difference is that if a futures trader wants to close out a position, an equal number of offsetting contracts for that commodity month is transacted and the original position is cancelled. Forward contracts are usually offset by establishing another forward contract position with terms as close as possible to those in the original contract. Unless the forward contract provides a method for cash settlement at delivery, this will potentially involve two deliveries having to be matched in the cash market on the delivery date.

To facilitate exchange trading, futures contracts possess a number of key features, especially standardization and marking to market. The elements of standardization provided by the futures contract and by the rules and regulations of the exchange governing such contracts involve: the deliverable grade of the commodity; the quantity deliverable per contract; the range of quality within which delivery is permissible; the delivery months; and, the options associated with the specific grade and date of delivery that is permissible. Standardization is achieved by making each futures contract for a given commodity identical to all other contracts except for price and the delivery month. In addition to standardization, forwards and futures also differ in how changes in the value of the contract over time are handled. For futures, daily settlement, also known as marking to market, is required. In effect, a new futures contract is written at the start of every trading day with all gains or losses settled through a margin account at the end of trading for that day. This method of accounting requires the posting of a “good faith” initial margin deposit combined with an understanding that, if the value in the margin account falls below a maintenance margin amount, funds will be transferred into the account to prevent the contract from being closed out. On the other hand, settlement on forward contracts usually occurs by delivery of the commodity at the maturity of the contract. Hence, futures contracts have cash flow implications during the life of the contract while forwards usually do not.

MODERN USAGE OF FORWARD AND FUTURES CONTRACTS

In modern markets, considerable variation is observed in the relative use of forward or futures contracting across commodity markets. For example, in currency markets, the large value and volume of many individual trades has the bulk of transactions for future delivery conducted in the currency forward market. Exchange traded currency futures contracts are an insignificant fraction of total trading volume in the global currency market. As trading in forwards is closely integrated with cash market transactions, direct trading in forward contracts is restricted to the significant spot market participants, effectively the largest banks and financial institutions. Because currency forward contracts do not have regular marking to market, restricted participation is needed to control default risk. As such, differences in the functioning of futures and forward markets impacts the specific method of contracting selected for conducting commodity transactions. For example, in contrast to forward trading, futures markets are designed to encourage participation by large and small speculative traders. The increased participation of speculators not directly involved in the spot market provides an important source of additional liquidity to futures markets not available in forward markets. In order to achieve this liquidity certain restrictions are imposed on trading, such as limits on position sizes and the imposition of filing requirements. By restricting participation to large players in the commodity market, many of the restrictions required for the functioning of futures markets are not present in forward markets.

FOUCAULT, MICHEL
1926–1984

Michel Foucault was a French philosopher who wrote widely on the history of thought. His influences include philosophers of science, such as his mentor Georges Canguilhem, but also Maurice Blanchot and Friedrich Nietzsche, from whom he derived his influential methodological notion of genealogy. Though Foucault's oeuvre treats seemingly disparate historical topics ranging from psychiatry to structuralism and on from sexuality to liberalism, a concern with the issues of knowledge and power as they constellation around the formation of subjectivities forms a constant, discernible thread.

Foucault's first major works are studies of psychiatry and mental illness. In Madness and Civilization (1961), Foucault examined how madness, the classical age inverse of reason, was systematized into the modern psychological category of mental illness. The Birth of the Clinic (1963) marks the beginning of Foucault's archaeological period, and examines the development of the perceptive apparatus of modern medicine. His attention to clinical confinement is demonstrative of his concern with dividing practices that progressively split certain individuals off from the social body.

The subsequent Archaeology of Knowledge (1969), Foucault's only methodological treatise, draws on the broad-sweep historiographical innovations of the Annales School to elaborate discursive formations as an analytical frame. In his archaeology of structuralism, The Order of Things (1966), Foucault historicized these discursive structures into distinct epistemes, which serve as the "condition of possibility" for knowledge. Tracing epistemic transformations in thought from the classical to the modern age, Foucault scrutinized the rise of man as the subject of the human sciences.

In his later work, Foucault shifted his approach to a process he called genealogy, which explicitly linked his analyses of knowledge to social structures of power. He argued against a purely repressive notion of power, elaborating instead on his oft-quoted maxim that "power is productive." In Discipline and Punish (1975), Foucault developed an explicit relationship between forms of knowledge of the body and the evolution of the modern prison system; disciplinary power, Foucault argued, arrays and organizes bodies into "analytical space," producing a logic that generalized itself from its application in concrete technologies such as the nineteenth-century Panopticon penitentiary to the level of society. In the first volume of his three-part History of Sexuality (1976), Foucault characterized disciplinary power as an anatomo-politics that operates on the level of the body, and juxtaposed it to its complement, bio-politics, which functions on the level of a population whose life forces it seeks to optimize. These populations, Foucault argued, are constituted in part via discourses about sexuality. In the second two volumes of his History, The Use of Pleasure (1984), and The Care of the Self (1984), Foucault turned to the processes of self-constitution in Greek and Roman sexual practices. The planned fourth and fifth volumes of the series remained unwritten upon Foucault's premature death at the age of fifty-eight.

Foucault's activism often related to the themes of his work. He advocated for penal reform and gay rights, and was associated with the anti-psychiatry movement. In his interviews and lectures, particularly those delivered at the Collège de France from the 1970s to 1984, Foucault reformulated many of the themes of his books into analyses applicable to the contemporary political situation. He responded to the ascendance of neoliberalism in the 1970s by refining his concept of bio-politics into that of governmental rationality operating in the realm of political economy.

Several scholars argued with Foucault over issues of historical accuracy, while others have contended that his attempts to transcend reason as the grounds of the subject's constitution remain methodologically fettered because they presuppose the existence of that self-same subject. Nevertheless, Foucault's many Anglophone interpreters have ensured the profound methodological and theoretical impact of his work in many disciplines, including anthropology, gender studies, history, literature, postcolonial studies, and sociology.

PRIMARY WORKS

FOUNDATIONS, CHARITABLE

Charitable foundations are endowments that are devoted to the pursuit of public purposes. Foundations are typically set up to exist, in principle, in perpetuity—spending parts of their annual income on public purposes, while retaining the remainder to preserve and grow their endowment assets. On occasion, however, donors limit the life span of a charitable foundation, requiring the foundation to spend out all assets over a given number of years, as was the case with the Julian Rosenwald Fund (1917–1948) and more recently the Bradley Foundation, established in 1985. Foundations have existed in one form or another for many centuries, and some observers have pointed to the Library of Alexandria and Plato's Academy (bequeathed with income-producing lands to his nephew) as early examples in antiquity. Historically, foundations were closely linked to religious charity in the Judeo-Christian tradition, but similar concepts are found in other religious traditions as well, such as the al-wakfiya in Islam.

In the course of the twentieth century, however, much foundation activity has been linked to the concept of philanthropy. Literally “the love of humankind,” philanthropy can be most poignantly defined as the use of resources to examine and address the causes of social ills or problems. As such, philanthropy contrasts with traditional charity, understood as the eleemosynary, ameliorative use of resources. Although many charitable trusts existed for various purposes in early American history, and the “foundations” of Benjamin Franklin (1706–1790), James Smithson (1765–1829), and George Peabody (1795–1869) were of great significance, the birth of the U.S. foundation sector, and with it the rise of the concept of philanthropy, is typically located around the beginning of the twentieth century.

In an influential series of articles published in the 1880s titled Wealth, the industrialist Andrew Carnegie (1835–1919) began to argue in favor of an obligation on the part of the rich to devote excess wealth to public purposes and to help provide opportunities for the less fortunate to better themselves. Over the following decades, the traditional focus of charitable trusts on providing relief and amelioration was gradually supplanted by a new orientation toward analyzing and addressing the causes of social problems rather than just addressing their effects. Using the emerging sciences to tackle the “root causes of social ills” set the ambitions and operations of the early twentieth-century foundations apart from earlier foundation activities in the United States and launched what historians Barry Karl and Stan Katz (1987) have termed the modern philanthropic foundation.

The earliest of these new foundations included the Russell Sage Foundation (1907), the Carnegie Corporation (1911), and the Rockefeller Foundation (1913), which popularized the foundation idea and provided a blueprint that other wealthy donors began to follow in the 1920s and 1930s. High marginal tax rates that originated during World War II (1939–1945) and continued into the postwar period, in combination with lax regulation, further propelled foundation growth in the 1940s and 1950s. By the 1960s, however, perceived economic misuses of foundations led to a political backlash culminating in the introduction of the new and relatively stringent regulation of foundations through the Tax Reform Act of 1969. This law instituted, among other provisions, a payout requirement for grant-making foundations that currently requires the annual payout in grants and other qualifying contributions to be the equivalent of 5 percent of the foundation's asset value. As such, the sum of foundation grants is closely tied to endowment value, and the run-up of the stock market in the 1990s—as well as the...
emergence of large-scale postindustrial philanthropists such as William Hewlett, David Packard, Bill Gates, Ted Turner, George Soros, and Warren Buffett—significantly increased the level of resources at the disposal of the foundation community at the beginning of the twenty-first century.

According to data provided by the New York–based Foundation Center, there were close to 68,000 grant-making foundations in the United States in 2005, holding aggregate total assets of close to $510 billion and spending $33.6 billion in grant and other expenditures. While the number of foundations had only doubled since the late 1980s (there were about 30,000 foundations in 1988), there was a dramatic acceleration of the financial means of the foundation sector in the space of only a few years. More specifically, total assets in nominal terms more than doubled between 1995 ($227 billion) and 2005, and grant dollars almost tripled between 1995 ($12.3 billion) and 2005. Despite this growth, funding patterns have remained stable: Education receives about 25 percent of all foundation support, followed by health with about 20 percent and human services with 15 percent. The other major funding areas are arts and culture and public affairs, with slightly more than 10 percent. The remainder is distributed between environmental causes, science, religion, and international affairs.

Although not insignificant, foundation resources remain overall rather limited. For example, the roughly $8 billion in annual educational spending by foundations equals no more than four times the 2005 operating budget of Harvard University or any large urban school district. As such, foundations are seldom the most appropriate vehicle to provide basic financing of educational ventures or scientific institutions or to serve as guarantors of sustainability over the long run. Rather, foundations have traditionally sought a different function. Faced with a scarcity of resources on the one hand, and flexibility and freedom from external constraints on the other, foundations are usually at their best when pursuing the development of new ideas and concepts. During the twentieth century, foundations had their greatest impact in fostering innovation and pioneering novel approaches and then moving on to different areas once the innovations took root.

This pioneering function of foundations is well reflected in the development of the social sciences in the twentieth century. The Russell Sage Foundation, founded in 1907 as the first of the great modern philanthropies with the mission to pursue “the improvement of social and living conditions in the United States,” adopted early on a focus on a scientific understanding of the causes of poverty. This led to the development of the social work profession, and eventually turned the foundation into the mainstay of social science inquiry that it remains today. Similar to the Russell Sage Foundation, but with more of an economics focus, was the Twentieth Century Fund (now the Century Foundation) founded in 1919.

Other foundations focused on improving education, including the Julius Rosenwald Fund in the American South, but the larger foundations, particularly the Rockefeller and Carnegie philanthropies, soon devoted growing shares of their resources toward the development of the social sciences. These foundations were instrumental in helping to establish new independent institutions that would shape social science discourse for decades, including the National Bureau of Economic Research (1920), the Social Science Research Council (1923), and the Brookings Institution (1927). Beyond building an institutional infrastructure, foundations also sponsored a range of important research studies, such as Gunnar Myrdal’s (1898–1987) seminal work on race in the 1940s, that gave prominence and helped validate emerging disciplines. All this work became crucial in consolidating the role of social science in the academy. After the Ford Foundation came to national prominence in 1949, fostering the social sciences was among its main programmatic objectives. Ford heavily supported social science development in European universities in the aftermath of World War II, and is widely credited with introducing area studies in the United States. Although federal funding has come to overshadow private foundation support for research, foundations have long shaped the development of the social sciences and remain important supporters of innovative work.

BIBLIOGRAPHY

The franchise, or the privilege or right to vote to elect public representatives or enact legislation, originated with the ancient Greek city-states of the fifth century BCE. As a political right, the franchise constitutes one of the core elements in modern citizenship, along with other political, civil, and social rights. In modern times the extension of franchise across European and North American nation-states marked the passage from a paternalistic form of government in the eighteenth century to the acceptance of the concept of citizenship, which is the foundation of democracy.

There has been wide variation across countries in the timing and regulation of the franchise. In most countries the franchise was extended gradually, as occurred in Great Britain, France, and the United States. In Finland, by contrast, it was extended all at once in the reform of 1906. The franchise may also be exercised at only certain levels of representation. In 1896, for example, women in Idaho were permitted to vote in school elections but not in state or federal elections, while women in Brazil were enfranchised in 1927 in the state of Rio Grande do Norte but not at the federal level. Since 2004 noncitizens in Belgium may vote in local elections only.

Where the franchise was extended gradually, voters entered the electorate in social groups. For instance, in Norway the franchise was extended to property holders in 1814, to manual workers and others in 1900, and to women in two stages in 1907 and 1913. Retractions of the franchise have also taken place. In France, for example, the franchise was granted to a large number of citizens in the late 1700s but was then severely contracted in 1815. Various qualifications have been used to regulate the franchise, including church membership, religious denomination, property ownership,纳税, literacy, a poll tax, residency, gender, and age. All such requirements have been aimed at disenfranchising different social groups at different times.

Franchise rules come about as a result of political conflict or as a by-product of conflicts over other issues. As E. E. Schattschneider points out in The Semisovereign People (1960), political conflicts that may produce franchise changes include political party competition, that is, from a conflict among governing elites for electoral advantage. In such cases extending the franchise to certain social groups may decide the outcome of elections to the advantage of the party or parties that appeal to the new voters. Franchise extensions may also be the product of conflict between governing elites and groups excluded from the electoral process, such as women or workers and their organizational representatives. Pressure from excluded groups may lead to franchise extensions by governing elites in an attempt to maintain the legitimacy of their governance (Freeman and Snidal 1982), especially when economic conditions or foreign policy objectives threaten the stability of the current political regime.

Conflicts over other issues, including economic conflict, may produce franchise changes as a by-product. For instance, international trade in nineteenth-century Europe and the United States, particularly the conflict between protectionists and free traders, is cited by Dietrich Rueschemeyer, Evelyne Huber Stephens, and John D. Stephens, the authors of Capitalist Development and Democracy (1992), as underlying the coalitions supporting or opposing franchise extensions. Opponents in the conflict devised franchise rules to change the balance of power in legislatures. Since about the mid-1900s democratic expectations have rendered the franchise a political right basic to democratic citizenship, so universal franchise with an age requirement has been generally granted automatically.

FRANCO, FRANCISCO
1892–1975
The Spanish general and head of state Francisco Franco may have been the weakest of the fascist dictators to take over a European power during the troubled peace that followed World War I (1914–1918), but once in office, he survived the longest. To be sure, the generalísimo gained control of his country only after a bloody civil war that prefigured the weapons technology, indiscriminate destruction, and mass executions of the world war to come. Yet, Franco’s survival instinct—for himself and for Spain—trumped whatever desire there was for vengeance or glory. During his sometimes violent forty-year reign as head of state, Franco nevertheless demonstrated sufficient tactical flexibility to keep his enemies divided and his country at peace.

Few incidents from Franco’s early career set him apart as a revolutionary. In fact, his rapid ascent in the Spanish army came largely from his willingness and ability to quell dissent. After graduating from the Infantry Academy (Toledo) in 1910, Franco sought action and advancement fighting rebels from 1912 to 1916 in Spanish Morocco, where he was seriously wounded. He recovered in time to lead Spanish Foreign Legion (Legión Extranjera) troops against Abd el-Krim (c. 1882–1963) in the Rif War (1921–1926). Back in Spain—as a young officer in 1917 and later as a fast-rising general in 1934—Franco led army efforts to repress striking workers. Shortly after the latter disturbance in Asturias, the center-right government in Madrid selected Franco as chief of the general staff.

However, as Franco rose in rank, his career tracked with the vicissitudes of the fragile Second Republic. In February 1936, a popular front on the left won close national elections, and Franco soon found himself reasigned outside mainland Spain to the Canary Islands. As violence and political assassinations on the left and right escalated in the summer of 1936, several generals plotted a coup to save Spain from communist and anarchist influences in the government. Within forty-eight hours after the coup was declared on July 17, Franco rejoined his colleagues and legionnaires in Morocco and became one of the leading figures in a conservative rebellion. By October 1936, Franco, invading from Morocco, captured the symbolic capital of Toledo. He was selected generalísimo of the Nationalist Army and shortly thereafter head of state for the new Spain.

Between July 1936 and April 1, 1939, the Spanish Civil War was hotly contested with neither side able to dominate militarily. Franco gradually pushed Republican forces into eastern Spain and managed to split them along a corridor to the Mediterranean in 1938, but the great cities of Madrid, Barcelona, and Valencia did not begin to fall until the end of January 1939. In the war, Franco stood out not so much for classic generalship but for his capacity to appreciate the mutual dependence of political and military strategy.

While his enemies suffered ideological divisions, Franco was able to unite Monarchists, Falange (Phalanx) elements, rural conservatives, and Catholics behind a single cause: keeping a united Spain out of the hands of leftist Republicans. He justified ruthless tactics, including siege warfare, aerial bombing of civilians, and summary execution, in the name of a holy crusade to save the state. He invited substantial foreign troops and equipment from Nazi Germany and Fascist Italy to crush democracy while preserving French and British neutrality. Even when they could not be subdued on the ground, Franco’s enemies were outflanked politically.

Pragmatism for the purpose of maintaining stability continued under Franco’s rule. Despite his pro-Axis leanings during World War II (1939–1945), Franco orchestrated a rapprochement with the United States, concluding economic and defense agreements with the Dwight D. Eisenhower (1890–1969) administration. Franco subsequently accepted innovations expanding tourism and joint production with foreign companies, which probably contributed to the Spanish Miracle, a long run of robust growth in the 1960s. Late in life, the dictator could not adjust to global waves of democracy and export-led expansion, both of which challenged conventions of state control, but his handpicked successor, Juan Carlos de Borbón y Borbón, would have more success after transitioning Spain back to constitutional monarchy.

The contrast between Franco’s leading biographer in English, Paul Preston, and revisionist historians such as Pío Moa demonstrates how Franco’s legacy depends on whether Nationalist tactics during and after the civil war are accepted as necessary evils. The generalísimo still rests with honors at the Valley of the Fallen, an enormous
shroud of gray stone that covers twenty thousand dead on each side. It stands as a symbol of unbending unity, but it also underscores for both Republican and Nationalist descendants the consequences of abandoning peaceful compromise. Such wide recognition has, in turn, underwritten a democratic constitution that celebrated twenty-five years in 2003 and set the political conditions for transforming economic growth in Spain, which from 1986 routinely outpaced fellow members of the European Union.

**FRANK, ANDRE GUNDER 1929–2005**

Andre Gunder Frank was born in Berlin on February 24, 1929. His parents first took refuge from the Nazis in Switzerland (1933), then later in the United States (1941). Frank obtained his undergraduate degree from Swarthmore (1950), and his PhD in economics from the University of Chicago (1957) under the supervision of Milton Friedman, whose neoclassical and monetarist development theory he would criticize throughout his academic life.

Initially a specialist in the economics of Soviet agriculture at Michigan State University (1957–1961), he soon left the United States for Latin America. While in Brazil, he influenced many economists, such as Theotonio dos Santos and Fernando Henrique Cardoso. After the coup d’état there in 1964, he went to Chile, where he joined the Center for Socioeconomic Studies at the University of Chile’s School of Economics. It was in Chile that Frank met his wife, Marta Fuentes—with whom he coauthored numerous publications—and where he developed his first series of books on socioeconomic conditions in Latin America.

In studies such as *Capitalism and Underdevelopment in Latin America* (1967), Frank argued both against the widely influential orthodox Marxist theory—which characterized Latin America as being in a semifeudal stage—and the Western-centric modernization theory, which considered the lack of development in the so-called “Third World” as a consequence of incomplete “modernization” and insufficient or backward capitalist institutions. Frank’s thesis of “development of under-development” essentially argued that since its very origins, Latin America had been exploited as a periphery by major colonial powers within the context of capitalist development across the Atlantic. By the early 1970s, Frank had become one of the predominant intellectuals articulating dependency theory, which claimed that external influences (e.g., political, economic, and cultural) on national development policies could explain why the third world, and Latin America in particular, had been and remained subordinate to Western interests (see, for example, Frank’s *World Accumulation, 1492–1789*, 1978).

Frank and others used the historical condition of dependency to explain why economic growth in the West does not translate into economic growth in the periphery: Even after colonies had gained nominal independence, colonial policies still linked the periphery to the world market by commodity chains, often through the export of single commodities with a low added value (raw materials). The metropolitan/satellite relationship between colonizer and colonized was an aspect of world-scale capitalist dynamics, not simply precapitalist imperialist history, and this relationship continues to impoverish the third world long after formal independence due to the existence of a local lumpenbourgeoisie, making it impossible for former colonies to catch up with the West. The latter then reinforces this neocolonization through its use of debt.

The military coup against President Allende’s socialist government (1973) drove Frank out of Chile. After returning to his native Germany to work at the Max Planck Institute (1973–1978), Frank subsequently accepted a position as professor of Development Studies in Social Change at the University of East Anglia (1978–1983), and then became professor of Development Economics and Social Sciences at the University of Amsterdam (1983–1994). It was during this period that he became affiliated with the world-system school and coauthored several studies with Immanuel Wallerstein, Samir Amin, and others on the dynamics of social crisis and social movements in the world system.

From the 1990s onward Frank adopted a revisionist approach to world history, rejecting world-system theory as well as most mainstream historical and theoretical interpretations as profoundly Eurocentric. Drawing on his previous studies of long-term economic cycles, Frank analyzed a 5,000-year-old trading system and argued, most notably in his influential *ReOrient* (1998), that the world
economy had been Asia-centered for thousands of years and was now moving back in that direction. In the last years of his life, Frank claimed that the recent rise of the West was a short-lived phenomenon due to a temporary decline of the East and that the analytical concept of capitalism had become meaningless.

When Frank died in Luxembourg on April 23, 2005, he had published over thirty-five books and hundreds of articles in dozens of languages. His contributions to the field of dependency theory and world-system theory influenced many in anthropology, sociology, political economy, and to a certain degree even liberation theology. His last interdisciplinary research agenda, cut short by his death, was an ambitious attempt to undermine Eurocentrism in both the field of history and in contemporary social theory. As much a social activist as an academic iconoclast, Frank was an intellectual who never quite received the recognition he deserved—yet his studies will continue to inspire many debates in the social sciences for decades to come.

FRANKFURT SCHOOL

The Frankfurt school refers to the members and associates of the Institut für Sozialforschung (Institute of Social Research) in Frankfurt am Main, Germany. The institute was established at the instigation of Felix Weil (1898–1975) as a privately endowed research foundation for the study of socialism within the University of Frankfurt in 1923. Prominent members of the institute included Max Horkheimer (1895–1973), Theodor W. Adorno (1903–1969), Herbert Marcuse (1898–1979), Leo Löwenthal (1900–1993), Friedrich Pollock (1894–1970), and Erich Fromm (1900–1980), and those associated with it included Walter Benjamin (1892–1940) and Siegfried Kracauer (1889–1966). During the period of the National Socialist (Nazi) regime in Germany, the institute, and its predominantly German-Jewish membership, was forced into exile, first in Geneva and subsequently in New York, where its members became affiliated with Columbia University. After World War II (1939–1945), the institute returned to Germany and reopened in Frankfurt in 1951, though some members, such as Marcuse and Löwenthal, chose to remain in the United States.

Between 1924 and 1930, the institute had close relations with the Moscow-based Marx-Engels Institute and was committed to the socioeconomic analysis of capitalism and such political issues as the crisis of the European labor movement. From 1931, under Horkheimer’s directorship, the school began to develop a distinctive theoretical framework, known as critical theory, that underpinned the diverse research programs to follow. At the epistemological level, the members shared the idealist tradition of continental philosophy, following in particular Immanuel Kant (1724–1804) and G. W. F. Hegel (1770–1831). In his inaugural lecture, however, Horkheimer urged the employment of critical theory in order to overcome the fundamental divergence between philosophical thinking and empirical inquiry. In contrast to traditional theory, typified in the positivist understanding of science, critical theory seeks to grasp the totality of society through interdisciplinary research and to provide an uncompromising critique of ideology.

At the level of social theory, the Frankfurt school was inspired by Marxism, in particular Georg Lukács’s (1885–1971) theory of reification, but the school was always highly critical of orthodox Soviet Marxism. The members of the institute rejected the simplistic doctrine of dialectical materialism, the mechanical application of a base-superstructure framework, and the role of the working class as the lone agent for social change. They strived instead to combine Marxist critique with Max Weber’s (1864–1920) understanding of rationalization and Sigmund Freud’s (1856–1939) psychoanalytic analysis of the individual.

Drawing upon this neo-Marxist perspective, the institute undertook research in three topical areas envisaged by Horkheimer and published them in their own journals, *Zeitschrift für Sozialforschung* (Journal of Social Research) from 1932 to 1939 and *Studies in Philosophy and Social Science* from 1939 to 1941. First, institute members...
searched for a comprehensive theory of contemporary postliberal capitalist society in terms of “state-capitalism.” Second, drawing on Fromm and Wilhelm Reich’s (1897–1957) social-psychological study of fascism and character, the institute investigated how individuals were integrated with so little resistance into a dominant system. This study became further developed in exile with the extensive research series Studies in Prejudice, which culminated in the collaborated work, *The Authoritarian Personality* (Adorno et al. 1950). Third, the institute saw the mass culture as central to a new configuration of the capitalist system, one that induced compliance with dominant social relations through culture and media, which Horkheimer and Adorno dubbed the *culture industry*.

Ultimately, the failure of the Weimar Republic, the emergence of totalitarian regimes in Europe, the Holocaust, and the self-destruction of Western “civilization” compelled the Frankfurt school to ask “why mankind, instead of entering into a truly human condition, is sinking into a new kind of barbarism” (Horkheimer and Adorno, [1947] 1997, p. xi). Horkheimer and Adorno found the answer lodged within a set of contradictions posed by an “instrumental reason” at the center of the Enlightenment project itself, providing a profoundly bleak and pessimistic diagnosis of modernity in the seminal collection of philosophical fragments, *Dialectic of Enlightenment* (1947).

After the institute’s return to Frankfurt, Adorno served as director from 1958 until his sudden death in 1969. During this period, the institute continued to elaborate the systematic social theory, particularly through the positivism dispute. As shown in Horkheimer’s *Eclipse of Reason* (1947) and Adorno’s *Negative Dialectic* (1966), however, their pessimistic perspective became more pronounced. In a continuing turn from the empirical-analytical sciences, Adorno increasingly focused on aesthetics and, in particular, the philosophy of music. His *Aesthetic Theory* (1970), published posthumously, clearly illuminates how the utopian dimension of critical theory rests upon aesthetic motifs—a dimension that also preoccupied Marcuse. The equivocal relation of the institute to radical social movements during the 1960s came to an end in January 1969 when Adorno called the police to eject student protesters occupying the institute’s Frankfurt premises. By contrast, in the United States, Marcuse’s distinctive social theory of liberation, greatly influenced by Martin Heidegger (1889–1976) and Freud, appealed to the New Left throughout the 1960s and early 1970s.

There have been significant—yet often marginalized—contributions to the development of the Frankfurt school and critical theory made by intellectuals more loosely associated with the institute: Walter Benjamin’s unique analysis of art and media; Franz Neumann (1900–1954) and Otto Kirchheimer’s (1905–1965) profound inquiry of political forms of integration in advanced capitalism; and Kracauer’s theory of film and propaganda. Jürgen Habermas, the most important representative of the second generation of the school, extensively criticized his predecessors’ oversimplification of modernity and developed a different analysis of capitalist society that appreciates the normative dimension of rationality rooted in communicative interaction. The Frankfurt school has also been criticized for its overly negative view of mass culture and its overestimation of the autonomous character of high art. More recently, Axel Honneth, who became director of the institute in 2001, has elaborated critical theory with a new focus on the social theory of recognition.

**Jae Ho Kang**
Benjamin Franklin was not only one of the best-known founding fathers of the United States, he was a leading politician, diplomat, writer, publisher, librarian, and philosopher. He was also a scientist renowned for his experiments with electricity and lightning, as well as an inventor credited with inventing the lightning rod, the heat-efficient Franklin stove, bifocals, swim fins, and numerous useful gadgets. His famous scientific experiment with a kite in a thunderstorm proved the presence of electricity in lightning.

Born into the family of a Boston soap maker and having received almost no formal education, in 1723 Franklin ran away to Philadelphia where he made his fortune first as a printer and later as the publisher and editor of the widely read Pennsylvania Gazette newspaper. He wrote numerous editorials, opinion pieces (usually under aliases), essays, and pamphlets about politics, economics, science, ethics, and civic self-improvement. He attracted attention for his wit and commonsense philosophy, especially as reflected in his proverbs in Poor Richard's Almanack, a popular yearbook on science and technology, which he published between 1733 and 1757 under the pseudonym Richard Saunders.

In 1731 Franklin helped launch the Library Company, the first subscription library in the United States. Twelve years later he helped found the American Philosophical Society, the nation's first learned society (a society that exists to promote an academic discipline or group of disciplines). While serving as a Pennsylvania assemblyman, he helped establish a local academy in 1751 that became the present-day University of Pennsylvania. He was a member of the Continental Congress, which appointed him to serve as deputy postmaster-general in 1753. At the 1754 Congress of Commissioners from the several American colonies held in Albany, New York, Franklin, though a loyalist, proposed a plan for the union of all the colonies under one government for the purpose of common defense and other general purposes.

In 1757 Franklin became a diplomatic agent in London representing Pennsylvania, Georgia, New Jersey, and Massachusetts, but he returned home in 1775 because of the revolutionary unrest in America and the so-called “Hutchinson affair.” Thomas Hutchinson (1711–1780) was the British-appointed governor of Massachusetts, who wrote to his friends in London to recommend curtailing the liberties of the American colonists. When Franklin obtained Governor Hutchinson’s letters, he leaked them to the press, causing public uproar in America. The British government angrily denounced Franklin in public and in 1774 removed him from the office of deputy postmaster-general and agent for the colonies, resulting in his final break with Britain (which he otherwise deeply admired). He served as a member of the Committee of Five, which had been instructed by the Second Continental Congress to draw up a document declaring independence from Britain. He helped Thomas Jefferson and John Adams, two other members of the committee, to draft the Declaration of Independence, which Congress unanimously adopted in 1776.

During the War of Independence (1775–1783) Franklin was the most popular foreign diplomat in the court of Louis XVI (1754–1793) in Paris, signing the 1778 Treaty of Alliance, which secured a close military-political alliance with France as well as substantial French military and financial help that made American victory possible. In 1783 he signed the Treaty of Paris, a peace treaty ending the war with Britain. Franklin came home in 1785 to serve as the appointed president of the Commonwealth of Pennsylvania. He was a delegate to the federal Constitutional Convention and signed the Constitution in 1787. His last great public service was authoring a major abolitionist pamphlet in 1789. His autobiography, first published in 1791, is acclaimed today as the greatest autobiographical work produced in colonial America.

Franklin was the most illustrious American of his time. As a philosopher of the Enlightenment, an eighteenth-century philosophical movement that rejected traditional ideas held at the time, he cast off all religious dogma but saw order and harmony in the universe. Rationalism, materialism, and belief in progress and social evolution mark all his publications. Prior to the revolution he believed that progress could be achieved under an enlightened monarch—especially through the inspiration and guidance provided by his own teachings, maxims, and aphorisms. Later he abandoned his doubts about democratic politics, rejecting the British monarchy and aristocracy in favor of the egalitarian view that all men are equal. In order to achieve progress and social harmony, he advocated the cultivation of practical virtues such as temperance, frugality, resolve, industry, sincerity, moderation, chastity, humility, and cleanliness. After the revolution he argued against the rule of the wealthy, taxation without representation, and slavery. He championed universal male suffrage, which he believed would encourage loyalty and respect for the law, as well as a unicameral federal legislature (without a Senate), which could prevent the rich from dominating political life and provide for a united, more efficient government. Scholars have also suggested that Franklin’s philosophy embodies the moral and political pragmatism of the American business class.

Frazier, E. Franklin

1894–1962

E. Franklin Frazier, one of the most prominent African American sociologists of the early twentieth century, studied at Howard University (BA 1916), Clark University (MA 1920), and the University of Chicago (PhD 1931). After completing his studies he spent most of his career at Howard University, where he became the chairperson of the Department of Sociology in 1934. He remained at Howard until his death. His central contribution to sociology was the formalizing of a research tradition on the African American family, which he first began to pursue seriously in his dissertation, “The Negro Family in Chicago.” That study resulted in a book of the same title, published in 1932. Frazier expanded his contributions on the topic by publishing The Negro Family in the United States (1939) and Negro Youth at the Crossways (1940). He also contributed to the field of race relations and race theory more generally, perhaps best exemplified by his publications “Sociological Theory and Race Relations” (1947) and Race and Culture Contacts in the Modern World (1957).

Frazier’s primary data sources were case histories and census statistics. Rather than employing micro-level analyses, however, he utilized this material to construct social organizational portraits of the African American family and, more generally, African American social life. As he conducted most of his research in the midst of the twentieth-century rural-to-urban migration of African Americans, Frazier’s social organizational perspective allowed him to offer robust and penetrating commentaries about the means of mechanisms of their adjustment to the hyper-industrializing urban sphere—the manner by which African Americans adjusted to industrialized urban societies after leaving the largely rural South. In doing so, he emphasized the social organizational shortcomings of the African American community as it transferred to a mostly northern and urban milieu.

Frazier essentially regarded African American migration to the city as an adaptational challenge for the black American family, and he argued that a history of social disorganization in the South, followed by turbulent efforts at reorganization in the nonsouthern, urban sphere, encapsulated the situation of the black American family’s confrontation with modern urban America. Frazier believed that the hardships of social and economic adjustment were the causal factors of crime, vice, illegitimacy, and delinquency. Because he asserted that social disorganization and pathology were a result of the African American community’s adjustment to new geographic terrain, Frazier was regarded by many later readers of his work as a pioneering conservative voice on the cultural dimensions of African American life. In fact, Frazier’s work has been regarded as the precursor to later works such as Daniel Patrick Moynihan’s highly controversial 1960s-era study “The Negro Family: A Case for National Action,” which argued that the pathology extant in lower-income African American families was largely due to the absence of an adult male figure.

Frazier was not a cultural theorist to the same extent as certain other scholars of African American life in the early twentieth century (e.g., Allison Davis, St. Claire Drake, W. E. B. Du Bois, and Zora Neale Hurston). However, his emphases in cultural analysis centered on what he perceived to be pathological and maladaptive dimensions of African American family and social life. His assertion that disorganization and pathology were prominent features of African American urban life was partly based on his embracing of the idea that African Americans did not retain any firm cultural roots in Africa. Thus, they were left without a rich, historically grounded cultural foundation in the United States, other than that produced in response to slavery. Accordingly, he regarded African Americans as consistently hampered by racism and social marginalization such that many developed cultural traits that were, if not fatalistic, at least certainly not conducive to social advancement in modern American society.

Quite early in his career, Frazier stressed the impossibility of African culture having endured the middle passage from Africa to slavery in the Western Hemisphere. He maintained this argument through investigations (albeit preliminary) of African American religious expression, social thoughts and ideologies, and social practices. Accordingly, he emphasized that the objective of formal education for black Americans should be to bind them to the American experience rather than aim to identify and proliferate some notion of cultural distinctiveness. Frazier’s logic in arguing that black Americans were, foremost, products of the American experience was grounded
in his consideration of the history of black Americans as a series of critical social shocks. The order of shocks was (1) the enslavement of blacks on the coast of Africa, (2) the middle passage, (3) the slave experience itself, and (4) a profound state of social disorganization following emancipation.

To Frazier, the product of this pattern of shock was a folk culture, largely exemplified by a southern-based, lower-income, black American constituency that was struggling to reconcile their awkward status in the American social landscape. In his doctoral dissertation and some early research, Frazier pointed out that the African American folk culture emanating from slavery and the postemancipation period was an expression of “surrender” to white America in terms of attitude and acceptance of life. He believed that this resulted in the black community’s durable designation as a subaltern caste in American social structure.

Frazier’s remedy for this condition was the cultivation of a form of race consciousness that could help fuel African Americans’ motivation for social advancement. However, Frazier maintained that an appropriate race consciousness was not grounded in a shared cognizance of primordially derived cultural characteristics; instead, he argued that it should take the form of a sociopolitical orientation that could motivate a downtrodden constituency in American society to improve its social status. Hence, for Frazier the significance of fostering race consciousness was not what it did to reify any notion of a distinct African American culture, but rather its use as a basis for asserting the growth and proliferation of pragmatic strategies for social uplift.

Despite what may appear to be an extremely critical perspective on the social and psychological dynamics of African American life, Frazier maintained that the conditions affecting the African American community were structural in nature and not in any way derived from inherent racial traits. Accordingly, despite the problems that African Americans encountered in adjusting to the urban sphere, Frazier asserted that this migration created opportunities for the social and cultural renewal of black Americans (especially as the urban terrain encouraged black Americans to break with the fatalistic folk culture proliferating throughout their southern, more rural, social experience). He also believed that a more constructive and positive race consciousness would develop due to the narrowing of social distance between African Americans in the urban domain. Finally, Frazier also believed that urbanization would destroy any retention of mythical notions of blackness that had been cultivated throughout history.

Frazier’s carefully nuanced approach to race consciousness was an indication of the nascent nationalist tendencies that underlay both his scholarship and his civic commitments. These tendencies emerged more directly in some of Frazier’s later work, especially his classic *Black Bourgeoisie* (1957), in which he argued that the African American middle and upper classes were engaged in forms of socialization and consumption parallel to those pursued by the mainstream American middle and upper classes. While Frazier did ascribe to the idea that black Americans had to assimilate into the cultural and social fabric of mainstream American society, he also maintained that such assimilation had to take shape in a critical rather than a mimical fashion. By that he meant that black Americans should not simply adopt the full range of cultural and social practices engaged by white Americans, but instead selectively appropriate those that would reap some clear benefits for black Americans in garnering firm and secure status in mainstream culture. Although it was widely read, *Black Bourgeoisie* was a highly polemic and, in comparison to Frazier’s other works, lightly researched commentary.

Because Franklin’s methodological tools were specifically suited for macro-level analysis, he was not well equipped to consider the personal situation of the black American. His objectives, however, did not necessarily concern that perspective. He viewed the black community as a caste constituency in American society. Therefore, his research emphasis was on the black American community as a whole, not its individual members. Moreover, his agenda for social change did not consist of strategies for individual adjustment to mainstream social and cultural patterns in American society; instead, he attempted to articulate a vision of racial advancement that could evaluate the entire population of black Americans.

To a large extent, under the auspices of Frazier and others of his era (e.g., Charles S. Johnson, St. Claire Drake, Horace Cayton, and Allison Davis) black American social thought moved from polemically oriented, philosophically grounded defenses of the humanity of African Americans to more formal scientific investigations, analyses, and model constructions of the state of the black American condition in a rapidly modernizing American society. Frazier’s assertions about African Americans’ loss of African cultural traits helped him to view the black American condition in terms of future possibilities—the most immediate being its complete and permanent stake in American society. Frazier’s commitment to this perspective was evident in both his scholarly pursuits and his political worldview.

FREE RIDER

The datum for any discussion on free riding and collective action is economist Mancur Olson’s (1932–1998) *The Logic of Collective Action* (1965). Olson’s thesis was a reaction to the pluralist view that when a political, social, or economic problem impinges significantly on the life of a citizen, he or she instinctively acts collectively on the basis of shared concern. Olson’s counterargument was that: (1) mobilization was not a natural or spontaneous process; (2) not all potential groups would materialize; and (3) membership would be lower than pluralists envisaged. Olson proposed that large numbers of rational potential members of groups seeking collective (nonexcludable) goods free ride these organizations because any benefits gained will be freely available to them without incurring the costs of membership. Indeed, as Russell Hardin (2003) notes “free riding [in large groups] is often clearly in the interest of most and perhaps all members.” Thus, for Olson, rational participators are special cases: they are either coerced to participate (e.g., compulsory membership as in trade union “closed shops”) or they are attracted by selective incentives only available to members. In small groups, free riding can be assuaged by the imposition of sanctions while free riders remain group members, or by excluding free riders (Page et al. 2005). As Page et al. highlight, “under favourable conditions, where the opportunities of entry and exit are symmetrically balanced, a process of voluntary association can mitigate the free-rider problem” (2005, p. 1032). Accordingly, “people are often observed to cooperate effectively in work groups, in local public goods provision, and in other settings” (Page et al. 2005, p. 1050).

Many scholars have argued that Olson’s work has been discredited (i.e., the collective action paradox has been negotiated) by several developments: (1) the advocacy explosion (that began in the mid-1960s) witnessed the emergence of large numbers of (public interest) groups that Olson said should not exist; (2) large numbers of citizens joined these organizations; and (3) numerous surveys demonstrate that members join for collective, not economically self-interested, ends. However, Olson’s rebuttal to these critiques was pointed and persuasive. He argued that many of these groups offered selective incentives to stimulate membership and that membership—and political lobbying—were in fact the by-product (i.e., not the primary reason for membership). He also maintained that membership levels in these groups were suboptimal—these entities mobilized only a small fraction of the latent membership—and many potential members choose to free ride. Accordingly, some interests would be underresourced in comparison with the public support they reflected, and other interests would be easier to mobilize (e.g., business).

Olson and supporters such as Hardin also argue that surveys of joiners reveal little about the larger group of those who refuse to join. Olson accepted that (trivial) numbers of members would join (in addition to those seeking selective benefits), but he argued that the number joining for collective goods would be dwarfed by those failing to participate. He cited two examples in support of this argument. First, he argued that “tens of millions of Americans” believed the population should not grow, but only a “miniscule minority of 12,000” were members of the group Zero Population Growth (Olson 1979, p. 149). Secondly, he (conservatively) estimated that more than fifty million Americans valued “a wholesome environment, but in a typical year probably fewer than one in a hundred pays dues to any organization whose main activity is lobbying for a better environment” (Olson 1982, pp. 34–35). For Olson, all these nonmembers are free riders.

Finally, it is worth highlighting that in his arguments Olson makes the loose assumption that those who in some general way support a cause, and do not join, are free riding. Critics argue that such ubiquitous labeling of nonparticipation stretches the free-riding concept too far. It does not necessarily follow, for example, that those who share a concern about the environment with members of environmental groups also agree with the goals or strate-
gies of environmental organizations, or believe that the groups’ activities will produce desirable outcomes, or consider the groups to be efficient (see Jordan and Maloney [2006] for a fuller exposition of this argument). Nonparticipation can emerge from noneconomically rational reasons.

FREE TRADE

Free trade refers to the unregulated exchange of raw materials, commodities, and services among people and nations. One of the foundational propositions of economic theory since the seminal work of Adam Smith (1723–1790) is that free trade is ultimately superior to protectionism if the principal economic objective is the greatest possible quantity of aggregate wealth or national income, and, indeed, the greatest good for all people. This proposition has widely and regularly been subjected to theoretical and political critique, and, despite the contemporary resurgence in free trade economics, free trade remains far more a theoretical ideal than an actual mode of economic practice and organization.

Before Adam Smith published his exhaustive study, The Wealth of Nations, in 1776, the mercantilist argument for the protection of markets largely dominated economic literature and practice. The mercantilists composed theirtracts during the seventeenth and eighteenth centuries, a period of tremendous colonial activity, trade growth, and, not coincidently, nation-state formation. Mercantilists predictably celebrated foreign trade but also believed strongly in the need to protect national industries and markets. They supported a wide range of protectionist measures, including tariffs on imports and subsidies for exports.

While few, if any, of the central ideas in Smith’s Wealth of Nations are original—many were asserted and developed by French physiocrats and British moral philosophers—he made a case for free trade that was and to a considerable degree remains incomparable in its rhetorical persuasiveness, thoroughness, and analytic precision.

Among Smith’s contributions was the theoretical refutation of the mercantilist argument for the promotion of exports and discouragement of imports, especially manufactured imports. Smith argued that the economy-wide impact of trade policies and regulations had to be examined. For instance, high duties on imports that were produced more cheaply elsewhere tended to diminish domestic competition and promote expansion of an inefficient industry. For example, protecting the British textile industry from cheaper colonial imports would lead to more investment of labor and resources in a demonstrably inefficient sector of the economy. Without protections, resources could be allocated to industries that were more competitive on the world market and which would thus realize greater economic aggregate growth, also known as static gains from trade.

Full analyses of the economic benefits of the division of labor and the public benefits of private self-interest were among Smith’s foremost contributions to free trade economics. The rewards from the division of labor are implicit in his argument for static gains: Nations that specialize in industries in which they are most competitive in unregulated conditions make the most efficient use of their labor and productive resources; thus both the specializing nations and the nations with which they trade will benefit. In the long term, these specialization-based static gains lead to dynamic gains; though dynamic gains are less clearly defined and more difficult to measure, they potentially accrue through the general economic impact of the more efficient use of resources.

The powerful case for free trade submitted by Smith was made into prescriptive economic doctrine by the next generation of economists, who further developed what came to be labeled classical economics. The most well-known figure is David Ricardo (1772–1823), who is generally credited with the theory of comparative advantage—in short, the idea that even nations that lacked absolute advantage (producing goods at the least possible cost) could still realize gains by concentrating on production of goods of
the greatest market competitiveness relative to other goods. Though Ricardo's name is most frequently associated with this theory, scholars are now more prone to give credit to James Mill (1773–1836)—father of another great and influential economist, John Stuart Mill (1806–1873)—for developing the most comprehensive explanation of comparative advantage among the classical economists.

In response to a vigorous public debate regarding Britain's protectionist Corn Laws, Mill explained that protectionist tariffs led to an absolute economic loss. Taxes on imported corn led to increases in the price of corn in Britain, which in turn led to an increase in the cultivation of less-productive land, which in turn increased the value and rent costs of land, which finally led to necessary wage increases. Thus, in protecting an inefficient product, a widespread set of increased costs ensued, netting a general or absolute loss. Resources would have been far better and more naturally invested in sectors of the economy that did not need to be protected because they were already competitive, or, in other words, sectors in which national comparative advantage already existed.

The doctrine of comparative advantage did much to establish free trade as the ruling economic orthodoxy for several succeeding generations of economists and, until the arrival of the Great Depression and the British economist John Maynard Keynes (1883–1946), it ruled economic theory (if not quite practice) with little exception. Two exceptions that received the most vigorous debate were related to “infant industries” and national defense. The infant industries argument proposed that new industries deserved some form of government protection until they had the chance to establish themselves as competitors in the global market. While his assertion was vigorously disputed, the idea was effectively made practice (to no small success) by Alexander Hamilton (1755/57–1804) in the early years of American national economic development. Also, in times of national emergency (e.g., war), interference in the workings of the free market was widely accepted as advisable. How, for instance, was supplying your enemy with goods for war to be justified? While wars may well be fought in the interests of the free market, the conditions and implications of war merit exception.

Whatever the sideline debates among economists regarding the particular cases for suspending the rules of free trade, it took the work of Keynes to establish a rigorous and widely accepted critique of free trade doctrine. Keynes, with considerable theoretical sophistication, faced the facts of the catastrophic market failure that goes by the name of the Great Depression and demonstrated the need to pursue protectionist measures. His General Theory of Employment, Interest, and Money (1936) included arguments for government spending on public works and promoting public investment and consumption during periods of high unemployment. Keynes did not believe that free market conditions realized, or “settled” at, full employment and that unemployment was a principal indicator of economic inefficiency. Government interventions in the market, including protective tariffs and subsidies, were, he asserted, sometimes necessary to restore employment and general economic health.

Keynes was enormously influential, not least in the United States, where his theories informed Franklin D. Roosevelt’s (1882–1945) massive government market intervention known as the New Deal. Toward the end of World War II (1939–1945), Keynes was a key figure at the meeting in Bretton Woods, New Hampshire, where two institutions were created that would come to dominate international economic relations in the later decades of the twentieth century: the International Monetary Fund (IMF) and the World Bank. However, these organizations, chartered under the banner of free trade principles, did not become important institutions of global economic management until after the cold war ended. Until the end of the cold war, the global free market was effectively compromised by the maneuverings of the superpowers as they intervened in the economic affairs of nations according to their particular national and ideological interests.

Since the cold war, the IMF and the World Bank, along with the World Trade Organization (WTO, established in 1995), have come to dominate the vigorous global articulation of free trade principles and practices. Throughout the cold war, developing nations were generally able to secure loans at very favorable terms, and banks were willing to lend freely under the assumption that bad loans would be covered by superpowers unwilling to see regimes fall to a competing ideology. When the cold war ended, the insecurity of these assumptions was revealed, and when bailouts were no longer forthcoming, debt crises struck developing nations hard. The World Bank and the IMF suddenly achieved a new relevance as they worked to negotiate debts no longer mediated by interested superpowers.

The terms demanded by the IMF and the World Bank for the renegotiations of loans were based firmly on free trade principles. These terms, which have been called structural adjustments, austerity measures, or conditionalities, have sparked spirited and sometimes violent debate. Nations, particularly the heavily indebted nations of Africa, Central and South America, and eastern Europe, in order to secure solvency loans, have been required to enact a host of free trade measures, including the devaluation of their currencies, removal of protective tariffs, reductions in public spending, and the privatization of key industries and services, including health care and education.

Those who dispute the effectiveness of these free trade conditions imposed on poorer countries argue that
the “conditionalities” have never been fully practiced by the wealthy nations whose representatives dominate the IMF and World Bank. They point out that at no time during the critical years when the United States or Britain were developing their economies were their currencies devalued or key social support programs privatized. These critics can also point to the vivid and devastating consequences of reductions in public spending, particularly in the area of health care in Africa. For their part, the supporters of free trade doctrines can point to the indisputable economic growth of such major nations as India and China. In the early years of the twenty-first century, it was reliably estimated that one million people a month were being pulled out of poverty by China’s embrace of the free market.

Though the neoliberal globalization of the free market increased rapidly after the fall of the Soviet Union and the opening of China to trade, the intellectual roots for the reemergence of free trade were established decades earlier in Europe and the United States. Important figures include the Austrian economist Friedrich von Hayek (1899–1992), who argued, in works such as The Road to Serfdom (1944), that any centralized control over social and economic matters would inevitably lead to totalitarianism. Even more influential was the University of Chicago economist Milton Friedman (1912–2006). Friedman was largely responsible for the shift in academic economics away from Keynesian ideas and toward monetarism, or the idea that money supply rather than employment should be the focus of economic policies. While Friedman’s monetarist theories have proved of dubious value, his attacks on virtually all forms of government regulation or even involvement in social and economic life have been very influential indeed. Throughout the years of the Margaret Thatcher and Ronald Reagan (1911–2004) administrations in the 1980s, the deregulations advocated by Friedman and his followers were aggressively implemented, and they established the political basis for the free market orthodoxy that dominates national and international economic affairs even to this day.

In the first decade of the twenty-first century, the principles of free market globalization almost exclusively govern the economic practices of nations and the institutions that administer the world’s economy, most notably the IMF, the World Bank, and the WTO. However, there are movements of national exception in countries such as Venezuela and Bolivia and activist assertions of dissent such as that expressed in the 1999 WTO protests in Seattle. A strong body of evidence now exists that the current free market orthodoxy has been implemented in ways that violate its core principles of economic freedom. This is especially evident in the removal of barriers to capital flows on the one hand but the increasing restrictions on the movement of labor on the other hand. Thus the North American Free Trade Agreement (NAFTA), negotiated among Mexico, Canada, and the United States and implemented in 1994, greatly increased the ability of goods and capital to move across borders even as the increasing militarization of the U.S.–Mexico border has made it more difficult for workers to pursue preferred employments. It remains to be seen if the current expansion of free trade ideas and practices will help or hinder the aspiration for the greatest common good that runs as a consistent theme in the writings of the movement’s best thinkers.

FREE WILL
SEE Existentialism.

FREEDOM
Freedom, the capacity for self-directed thought and action, and the choice of one’s own goals, is one of the central values of western thought. Often closely tied to questions of free will, freedom is also seen as central to questions of moral responsibility, personality, and identity, and to democratic political life. Rule by others, such as
political domination as well as social oppression, through established forms of authority or psychological restrictions, are all opposed by forms of freedom. The idea of liberation from the limits of nature of entrenched authorities or despotic rulers is a central theme of both literature and politics.

Freedom does not have a simple or single essence. It has developed sometimes haltingly in the history of thought. For the ancients, freedom was not equated with worldly accomplishment or goal-directed action; it was primarily an inner state of being. The free person was one who rules his desires (freedom applied mostly to males) rather than being ruled by them. For Plato, freedom meant to be liberated from base desires. Rather than a life of self-chosen ends, however, the ancients saw the highest form of life as contemplation of the order of the universe. The free man was released from desires that impeded this goal.

The Greeks originated the political idea of self-rule (koinonia), but generally applied it only to a limited group of male, property-owning citizens. In Aristotle’s political philosophy, freedom requires active participation by citizens in the life of the polis. This, too, is not a form of goal-directed action, but of acting in concert: The citizen alternates with others in holding office and engages in deliberation about laws and public affairs. Although there were examples of wider democracy in ancient Greece, political theorists such as Aristotle supported a limited republican form. Only propertyed male heads of household had the requisite self-control over their own desires to be capable of self-rule, they believed; the rest were only fit to be ruled by others. The Stoics living under the Roman imperium reemphasized a purely inner freedom based on deliberate self-mastery. Still, the Stoics also had early notions of a cosmopolitan humanity in which all were naturally equal.

The roots of the modern notion of freedom can be traced back to the late Middle Ages. The rise of independent city-states in Italy and other parts of Europe was accompanied by a revival of ancient republicanism. These newer forms of republicanism were more disposed to give a role to the people and inclined to stress liberty. The later Middle Ages also provided some sources of the modern notion of individuation. The Renaissance that followed developed a modern idea of the self as a “work of art,” and the development of individuality was the essence of freedom. In the seventeenth century there was a further elaboration of republican thought that stressed the relation of a free people to the new ideals of liberty.

LIBERAL THEORY
Modern philosophy rejected the idea that knowledge of the structure of the world could and must be achieved through individual human reason alone. Revealed religion or other idols had to be rejected. Although this philosophical ideal first justified only free scientific inquiry, it proved useful for politics as well. But the most influential notions of freedom in modernity are those associated with liberalism. Whereas the Aristotelian tradition saw humans as naturally political animals who realized their aims in community, the modern liberal view saw individuals as possessing natural liberty, prior to social relationships or attachments. Although this is certainly a fiction, it reflects the idea that the individual—not the social environment, the church, the state, or the family—is the source of social and political freedom. These forms of social and political freedom are now seen as a form of self-determination: the capacity to choose to decide upon and pursue one’s own goals or plans of life. The individual is an active agent whose freedom is seen in accomplishments. Freedom is also the ability to act freely to achieve these goals. The republican emphasis on deliberating with others was replaced in the philosophies of Thomas Hobbes and John Locke by notions of self-interest. This conception was often linked to the new scientific consciousness, in which the individual was like all other things: a mechanism driven by material pursuit of interest, not by spiritual causality or teleology.

The liberal notion of freedom made a strong distinction between the public and the private that was quite different from what the ancients had conceived. Whereas Aristotle thought that freedom required public participation, liberals saw freedom first of all as applying to the private individual, who is free to act. Here freedom is the absence of constraint, or freedom from something. The idea of the social contract expressed the fact that legitimate political order is based on the freely given consent of the governed. This premise, emphasizing the equality and freedom of all, is the foundation of most modern democracies, where individuals are natural bearers of rights and freedoms that cannot be taken away by governments. In some respects, the liberal model of freedom as self-determination is restricted when combined with an economic model of human action, where the individual is a consumer rather than a creator, one who chooses between products on the market. As a maximizer of goods, the individual is primarily a possessive individual.

DEVELOPMENTAL THEORY
The theory of Jean-Jacques Rousseau was important in the development of a second conception of modern freedom. Rousseau held that the social contract (rejected by republican theories) was more than a contractual agreement—it created a general will that was the expression of a common moral will. In the romantic period this conception became what has been called a “developmental view of freedom.” The Romantics rejected the Enlightenment view of man,
which was overly rationalist and mechanistic, and sought a broader notion of human freedom that stressed aesthetic and relational qualities of freedom. In the developmental view, humans express their freedom through the development of all their human powers, Freedom is self-realization, or positive freedom. Karl Marx’s notion of freedom embodied this view when he invoked the all-around development of capacities. Human action is not simply goal-directed, but includes many forms of human expression: artistic, expressive relations to others, and play, to name a few. Although this view draws on the Aristotelian tradition, it differs from it in its stress on individuality and its adoption of the modern view of the open-ended nature of capacities.

Developmental theories reject the atomism of liberal theory. They stress the interdependency of human activity. The development of freedom and capacities is not the result of individual initiative alone, but rather relies on a backdrop of prior social conditions: We are vulnerable, depending on a wide variety of conditions to develop and employ our human capacities.

Developmental theories have been central to radical democratic socialist and social democratic conceptions of politics. Stressing the role of active citizen participation in politics, they agree with Aristotle that the fully realized individual has to be a participant in his or her own governance. Socialists extend this equal participation to models of economic production and reject liberal emphasis on private property. Socialized production, accordingly, is central to the development of selfhood and individuality.

For socialists and social democrats, political freedom rests on prior social freedoms, including a minimum of economic equality, retirement and unemployment benefits, health and safety, and other measures of human welfare. Conditions of complex human freedoms have become important not only for socialist states, but also for modern social democratic welfare states.

Critic of developmental views often have held that Rousseau’s ideal of the general will have inherently totalitarian elements that are contrary to the liberal ideas of individual freedom. They also criticize the idea of inner powers unfolding in a natural manner. Others see expressive freedom as a socially pathological emphasis on pleasure or aesthetics for its own sake. The exclusive stress on aesthetic freedom reduces the influence of the work ethic and moral responsibility on human conduct.

COMMUNICATIVE FREEDOM
A third notion of freedom responds to recent concerns with cultural integrity, identity politics, and recent social movements, and new conflicts over the ability of participants to form their own unique relations to themselves and to social worlds. Influenced by the growing emphasis of language as central to philosophy and social science, ideas of communicative freedom have become an important element in contemporary debates. Communicative models stressing individual self-realization take place in a context of intersubjective community. Extending the liberal idea of free speech and expression, freedom involves the very capacity to communicate in language to formulate and express ideas in discussion, but it also is an element in the formation of the identity of individuals and groups. This capacity can be impeded by forms of authority and power that exclude us from discussion and deliberation, or distort our relations to ourselves and others. Deliberative models of democracy attempt to remedy some of the deficiencies of liberal and republican notions by stressing the centrality of discursive rationality.

In the mid-nineteenth century Alexis de Tocqueville raised an objection that has persisted to the present. Although de Tocqueville generally approved of new democracies, as represented by the young American state, he raised questions about the quality of democratic citizens as conformist and mediocre. Democracy may increase political freedom, but it also leads to impoverished personality. At the end of the century Friedrich Nietzsche provided a more aggressive critique of democracies. Opposing the abstract individual of liberal theory and the Protestantism underlying Immanuel Kant’s notion of autonomy, Nietzsche argued that religion (namely Christianity) produced meek unfree subjects who feared authority and lacked the qualities needed for heroic struggle.

A third objection focuses on the distortions of democratic freedoms inherent in the concentration of power in mass democracies. Agreeing with developmental democrats such as John Stuart Mill and John Dewey that democratic citizenship requires an educated and informed public, critics argued that mass democracies are characterized by a manipulated mass culture. This mass culture is a product of the ownership and concentration of media in the hands of powerful economic and political interests that maintain their power positions, restricting political and social freedom, by controlling the production and reception of information. Access to the means to make sense of and deliberate about public issues remains a major concern for the health of democracies.

Max Weber’s work on rationalization and bureaucracy raised another concern over the compatibility of large liberal democracies and freedom. Weber saw in social rationalization the increasing centrality of instrumental rationality. Bureaucratic authority became prominent in political regulation for reasons of efficiency or technical expertise, and it has come to displace not just deliberation and citizen participation but also the development of per-
sonality and social freedom. Bureaucracy itself further interprets the needs identified by developmentalists in an instrumental fashion, with resources of money or power rather than freedom or mutual understanding; citizens become subjugated clients and dependents.

In complex modern societies, democracies have grown in territory and population. The possibility of face-to-face democracy—the “town meeting” tradition with its stress on citizen participation—is difficult to maintain. Most modern democracies are representative, but the process of representing the varied subpublics of a democratic public can lead to conflicts. For critics, liberal and pluralist democracies are also thought to be dominated by interest groups and hence incapable of formulating a common good. Individual freedom does not lead to social or political freedom. This objection, which comes from all political outlooks, tends to see liberal democracy as a form driven by self- and group interests. For example, the conservative jurist Carl Schmitt thought that parliamentary systems were unworkable because of the conflict of interest groups, and contemporary communitarians see liberalism as lacking any orientation to a common good or moral core. This objection has some merit. Many proponents of the interest-group position devalued citizenship—already little more than voting. For some proponents, nonparticipation in even a minimum of democratic citizenship is seen as dysfunctional or unnecessary.

Conservative and communitarian objections, however, require a notion of sociocultural unity or homogeneity that is incompatible with the diversity of publics found in multicultural societies. These new challenges to liberal democratic society reflect a conflict between the claims of cultural integrity, which is not generally acknowledged in classical liberalism, and civil and political rights typical of liberal democratic notions of freedom. They also apply to newly important categories such as gender. Other conflicts between a developmental politics of distribution and the newer politics of resignation raise questions of the ways that liberal democracies reconcile the needs for solidarity, which are necessary for communicative freedom, with other freedoms producing a conflict between developmental politics of distribution and the newer politics of recognition. How do liberal democracies reconcile the need for solidarity, which is necessary for communicative freedom, with other freedoms? The renewal and reform of freedom in modern democratic societies rest with the healthy respect for and space for political protest and dissent. Freedom is not a fixed essence; instead, it has to be renewed and transformed in ever-changing social circumstances. Social movements have instituted new regimes, as in revolutions, but also have pressed claims for rights in established democracies, as in labor movements, movements for equal rights for women, racial minorities, and gays and lesbians, and even antitwar movements. The ability of a society to respond to dissent and protest is an important feature of a functioning democracy. In modern societies this often goes beyond mere tolerance to what postmodernists have called “openness to the other.” Societies have to recognize that dissent takes place in the context of a broader solidarity; we have to be aware of and open to others who seem different, yet we must also accept the need for discussion that may or may not vindicate their claims.

Cultural movements can also be sources of freedom movements. These can often be generational conflicts, as in the Sturm und Drang movement in Germany in the romantic era, and the counterculture movement in the 1960s. Both of these challenged what they saw as repressive social and cultural practices well before they became forces for political change. It could also be argued that cultural resistance had a decisive role in maintaining subterranean political resistance in Eastern Europe prior to the fall of Soviet Communism.

A deliberative model of democracy employing the insights of communicative freedom seems to propose a different model of democratic freedom. Political order is not constituted by a unified general will, but by a web of symbolic interactions in which solidarity and commonality is established through participation in social and political life, not in a reestablished common good. A healthy democracy requires a well functioning parliamentary or representational system, and significant civil rights and economic and social equality. But it also requires a substantial measure of private and public freedom, supported by extra-governmental publics who are able to discuss and actively challenge existing practices. It has to pay equal attention to the claims of solidarity and cultural integrity. It requires a greater interchange between the knowledge of experts and the judgment of citizens in the formation of policy and the formation of public policy. It also requires a truly democratic educational system open to all and a free system of media that promotes knowledge and discussion of significant issues.

Theories of freedom are associated with different institutional arrangements for the maximization of freedom. Theories of negative freedom have been linked most often to liberal political institutions such as constitutional governments with representative political institutions; elected representatives; free, fair, and frequent elections with a competitive party system; and an independent judiciary; along with extensive freedom of information and communications and a network of voluntary associations.

Developmental theorists argue that the institutional framework associated with negative freedom tends to negate the very conditions of freedom that it intends to facilitate. When combined with market economic institutions, liberal political institutions create large-scale...
inequalities of economic and social power that make the exercise of equal liberty impossible. Poverty, powerlessness, and forms of disrespect all combine to make the exercise of freedom difficult. A commitment to freedom requires maintaining a minimum satisfaction of human needs. In market societies, developmentalists have advocated extensive welfare measures to compensate for the effects of power. They contend that rather than restricting freedom, as classical and neoclassical liberals might think, extensive public support in fact enhances freedom, by providing a basis for equal employment to all. However, for developmentalists, such institutions have to include the promotion of civic equality as well. Developmentalists go beyond welfare-state reform to advocate replacing the private-property market system with social production, or radically democratizing areas of work education and communications.

Despite the triumphalism of neoclassical liberals in the post–cold war era, democracy has not increased. Only about half of the world’s nations, consisting of less than half its population, can be considered democracies, and all of them do not meet all the criteria discussed above. The dissolution of the Soviet Empire has led to a rise in fundamentalist movements and ethnic conflicts that threaten to undermine democratic institutions in some newer states and to prevent their establishment in others. Some well established democracies have succeeded in accommodating ethnic diversity by forming “consociation democracies,” but these require special conditions not achievable in all countries. Attempts to design constitutions or democratic institutions through planning or by “shock therapy” have not led to large-scale democratic movements in these countries—they have simply reinstituted the pathologies already present in advanced societies.

Pathologies of democratic freedom have sometimes resulted from restricted conceptions of representative institutions in the twentieth century. Examples include competitive elitism, which reduces democracy to a form of choosing leaders, and corporatist representation, which limits popular participation and substitutes consultations with large organized groups. Although contemporary democratic societies provide some room for competing groups, they are characterized by deepening asymmetries of power and wealth that limit the effective equal freedom of all. Actual capitalism, unlike the myth of self-equilibrating markets, requires concentration of economic and social power. The growth of corporations beyond nation-states is another important factor in the growth of poverty and income disparity. Many commentators question whether the nation-state and its conception of democratic freedom is a feasible model in light of the increasing global power of corporations. The nation-state, it is argued, no longer has the autonomy from the economic system to direct its own affairs and achieve its own goals.

In the developing world democratic freedom faces these obstacles and others. The subaltern economic status of developing nations has made them vulnerable to forced political and economic restructuring in order to obtain funds for development projects, and for the most part, attempts to create a civil society from above by local leaders or outside groups has led to limited democratization with a limited role for popular democratic initiatives.

FREEDOM OF INFORMATION ACT

Signed into law by President Lyndon B. Johnson in 1966, the U.S. Freedom of Information Act (FOIA) gives the public the right—within certain bounds—to be provided federal government records on request. The FOIA requires every department and agency in the executive branch (except for the president and the president’s immediate advisors) to make duly requested government records “promptly available to any person.” The law exempts several categories of government records from release, including records relating to classified defense and foreign policy matters, law enforcement records whose release would interfere with investigations and prosecutions, and records considered internal agency memoranda. The FOIA does not apply to Congress or the federal courts.

The key figure in the development and passage of the FOIA was Congressman John E. Moss, a California Democrat. As chair of the House Special Subcommittee on Government Information, Moss spent eleven years presiding over hearings and publishing reports that exhaustively documented the secrecy practices of the executive branch. Remarkably, his work drew little interest or support from members of the Washington press corps, who at that time were accustomed to a collegial, nonadversarial relationship with government officials. Thus, the bill’s passage can be largely attributed to the diligent legislative maneuvering of Moss—as well as his party’s control of both the presidency and Congress (by large majorities in the House and Senate) in 1966.

Controversy about the FOIA’s implementation arose almost immediately after it became law, and the tenor of this debate has remained consistent over time. On the one hand, requestors of information have complained about delays in receipt of records, fees charged for duplication, and improper invoking of exemptions. On the other hand, agency staff and some elected officials have questioned the expenditure of significant resources required to comply with the law. All these concerns have shaped revisions and amendments to the FOIA, which has been significantly modified three times (in 1974, 1986, and 1996).

Records obtained under the FOIA are central to hundreds of news stories about the government that appear in the media each year. The FOIA thus plays an important role in efforts to keep government activity transparent and accountable. However, only a small proportion of FOIA requests are made by news organizations and legitimate researchers. A great number of requests are filed by commercial interests, who hope to repackage and sell the information obtained from their requests, or otherwise use it for business purposes. Access to government records has been dramatically altered by the diffusion of information technology. The vastly reduced cost of indexing, reproducing, and transmitting government records has made it easier for the public to locate and access government information—but it also makes it more conceivable that information of a sensitive or classified nature will fall into the wrong hands.

The FOIA has inspired the passage of similar legislation by U.S. state and local governments. Throughout the world, democracies both new and old adopted freedom of information (FOI) laws in the late twentieth century—many that consciously emulated the U.S. law. But FOI laws by themselves do not lead to greater government accountability. To have much effect, FOI laws require a media that is unhesitant to investigate government activity and is willing to use these laws as a tool to do so.

FREIRE, PAULO

1921–1997

Until his death from a heart attack on May 2, 1997, Paulo Freire devoted his life and work to a philosophy and practice of education committed to the empowerment and
social transformation of communities marginalized by poverty, colonialism, and political repression. Freire worked extensively in Brazil, Chile, and West Africa, where he developed a method for teaching literacy to poor, working class, and indigenous people. The development of Freire’s ‘pedagogy of the oppressed’ cannot be viewed in isolation from his experience of life in Brazil during the first half of the twentieth century. Born in 1921 in Recife, a port town in the northeast province of Pernambuco, Paulo Reglus Neves Freire was raised in a middle class family that experienced severe poverty during the Great Depression. Poverty and hunger during Freire’s youth caused several setbacks in his formal schooling, an experience that shaped the later development of his educational philosophy. Freire studied law at the University of Recife, but gave up his career as a lawyer after his first case to teach Portuguese in secondary schools (Gadotti 1994). Freire married Elza Maia Costa de Oliveira, a primary school teacher, in 1944. Throughout their marriage, Elza encouraged and inspired Freire to devote himself to his work in the field of adult education.

Northeast Brazil in the early 1960s was a region of acute social polarization and economic suffering. It was during this time that Freire began to elaborate a model of politically engaged pedagogy against the prevailing “culture of silence” under which the illiterate poor labored. He emphasized the dialectic relationship between theory and practice, which is expressed through three generative themes in his work: conscientization, dialogic learning, and his critique of the banking approach to education. Underpinning these three generative themes is a student-centered system of learning that challenges how knowledge is constructed in the formal education system and in society at large. Freire’s student-centered approach stands in stark contrast to conventional educational practice, which he referred to as the “banking approach” to education. He argued that conventional learning was the tool of the elite because it treated students as objects upon which knowledge is “deposited.” Genuine learning, for Freire, could only be achieved through lived experience, critical reflection, and praxis (Aronowitz 1993, p. 9).

The idea that “experiences are lived and not transplanted” is a central tenet of Freire’s philosophy (Gadotti 1994, p. 46). Conscientization is the key process by which students develop a critical awareness of the world based on the concrete experience of their everyday lives. The development of critical awareness through conscientization alters power relations between students and teachers, the colonized and the colonizer, thereby transforming objects of knowledge into historical subjects (Freire 1997). Freire proposed that a dialogical theory of action based on communication and cooperation was necessary not only for understanding the mediating role of historical, colonial, and class relations (conscientization), but also for the active work of changing them. Dialogic action challenges mediating social realities by posing them as problems that can be analyzed critically by those who have direct experience of them. Dialogue becomes a form of collective praxis directly concerned with unveiling inequitable conditions obscured by the ruling classes.

The success of Freire’s method for teaching literacy to Brazil’s impoverished citizens, coupled with his efforts to affect social and political change among the landless poor, led to his imprisonment after a reactionary military coup in 1964. He spent a total of seventy days in jail. After his imprisonment in Brazil, Freire was exiled to Chile, where he remained for five years before taking up posts at Harvard University and in Switzerland. He did not return to Brazil until 1980. Freire’s most famous book is Pedagogy of the Oppressed, originally published in 1970. Other key works include Cultural Action for Freedom (1972), Education: The Practice of Freedom (1976), and Pedagogy of the Heart (1997). Thirty years on from his most influential work, the commitment to education as a pathway to liberation that Freire helped inspire remains a vibrant part of the social justice campaigns of grassroots activists, social policymakers, educators, and scholars (see McLaren 2000).

FRENCH REVOLUTION

The French Revolution invented modern revolution—the idea that humans can transform the world according to a plan—and so has a central place in the study of the social sciences. It ushered in modernity by destroying the foundations of the “Old Regime”—absolutist politics, legal inequality, a “feudal” economy (characterized by guilds, manorialism, and even serfdom), an alliance of church and state, and created a vision for a new moral universe: that sovereignty resides in nations; that a constitution and the rule of law govern politics; that people are equal and enjoy inalienable rights; and that church and state should be separate. That vision is enshrined in the Declaration of the Rights of Man and Citizen of 1789, whose proclamation of “natural, imprescriptible, and inalienable” rights served as the model for the 1948 United Nations Universal Declaration of Human Rights.

Eighteenth-century France experienced overlapping tensions that erupted in revolution in 1789. First, the Enlightenment contributed to an environment in which revolution was possible by its insistence on reforming institutions to comply with standards of reason and utility. Furthermore, it coincided with the rise of public opinion, which undermined the absolutist notion that political decisions required no consultation or tolerated no opposition. Second, the French state faced bankruptcy because of a regressive and inefficient tax system as well as participation in the Seven Years War (1756–1763) and the War of American Independence (1775–1783). Third, France witnessed endemic political strife in the eighteenth century. Technically absolutist monarchs who ruled by divine right and who exercised sovereignty without the interference of representative institutions, French kings in reality met with opposition to their policies from the noble magistrates of the highest law courts (Parlements), who resisted fiscal reforms in the name of protecting traditional rights from arbitrary authority. Finally, while class conflict did not cause revolution, there existed stress zones in French society, as a growing population threatened many people with destitution and as talented commoners chafed at their exclusion from high offices in the church, state, and military. Economic problems intensified after bad weather doubled the price of bread in 1789.

These tensions reached a crisis point in the “prerevolution” from 1787 to 1789. To deal with impending fiscal insolvency, the government convened an Assembly of Notables in 1787 to propose a new tax levied on all land and the convocation of advisory provincial assemblies. Repeated resistance to reform by the notables and Parlements forced Louis XVI (ruled 1774–1792) to convene the Estates-General, a representative body composed of clergy, nobles, and the Third Estate that had not met since 1614. The calling of the Estates-General in 1789 led to a debate over the leadership of reform, and France’s struggle against royal despotism soon became a struggle against noble and clerical privilege. In this context, Emmanuel Sieyès’s pamphlet “What Is the Third Estate?” galvanized patriot opinion by responding “Everything!” and by portraying the privileged groups as unproductive parasites on the body politic.

During a stalemate over whether the estates should vote by order or head, the Third Estate claimed on June 17 that it formed a National Assembly with the authority to write a constitution. This step transferred sovereignty from the king to the nation and constituted a legal revolution. The legal revolution was protected by a popular revolution on July 14 when the people of Paris stormed the Bastille fortress in search of weapons. Popular participation continued to radicalize the revolution. In the countryside, a peasant insurgency against manorial dues and church tithes prompted the National Assembly to decree the “abolition of feudalism” on August 4.

The revolution had three phases. The liberal phase found France under a constitutional monarchy during the National Assembly (1789–1791) and Legislative Assembly (1791–1792). After the destruction of absolutism and feudalism, legislation in this period guaranteed individual liberty, promoted secularism, and favored educated property owners. The aforementioned Declaration of Rights proclaimed freedom of thought, worship, and assembly as well as freedom from arbitrary arrest; it enshrined the principles of careers open to talent and equality before the law, and it hailed property as a sacred right (similarly, the National Assembly limited the vote to men with property). Other laws, enacted in conformity with reason, contributed to the “new regime.” They offered full rights to Protestants and Jews, thereby divorcing religion from citizenship; they abolished guilds and internal tolls and opened trades to all people, thereby creating the conditions for economic individualism; they rationalized France’s administration, creating departments in the place of provinces and giving them uniform and reformed institutions. Significantly, the National Assembly restructured the French Catholic Church, expropriating church lands, abolishing most monastic orders, and redrawing diocesan boundaries.

The revolution did not end despite the promulgation of the constitution of 1791. King Louis XVI had never reconciled himself to the revolution and as a devout Catholic was distressed after the pope condemned the restructuring of the church (known as the Civil
Constitution of the Clergy). Ultimately, the king attempted to flee France on June 20, 1791, but was stopped at Varennes. Radicalism constituted another problem for the assembly, for Parisians and shopkeepers (called sans-culottes) resented their formal exclusion from politics in the Constitution and demanded legislation to deal with France’s economic crisis and the revolution’s enemies, particularly nobles and priests. After Varennes, radicals called increasingly for a republic. In addition, revolutionaries’ fears of foreign nations and counterrevolutionary émigrés led to a declaration of war against Austria in April 1792. France’s crusade against despotism began badly, and Louis XVI’s veto of wartime measures appeared treasonous. On August 10, 1792, a revolutionary crowd attacked the royal palace. This “second revolution” overthrew the monarchy and resulted in the convocation of a democratically elected National Convention, which declared France a republic on September 22, 1792, and subsequently tried and executed the king.

The revolution’s second, radical phase lasted from August 10, 1792, until the fall of Maximilien Robespierre (1758–1794) on July 27, 1794. The Convention’s new declaration of rights and constitution in 1793 captured the regime’s egalitarian social and political ideals and distinguished it from the liberal phase by proclaiming universal manhood suffrage, the right to education and subsistence, and the “common good” as the goal of society. The constitution, however, was never implemented amid the emergency situation resulting from civil war in the west (the Vendée), widespread revolts against the Convention, economic chaos, and foreign war against Austria, Prussia, Britain, Holland, and Spain. Faced with imminent collapse in the summer of 1793, by spring 1794 the government had “saved” the revolution and organized military victories on all fronts. The stunning change of events stemmed from the revolutionaries’ three-pronged strategy under the leadership of Robespierre and the Committee of Public Safety. First, they established a planned economy, including price controls and nationalized workshops, for a total war effort. The planned economy largely provided bread for the poor and matériel for the army. Second, the government forced unity and limited political opposition through a Reign of Terror. Under the Terror, the Revolutionary Tribunal tried “enemies of the nation,” some 40,000 of whom were executed—often by guillotine—or died in jail; another 300,000 people languished in prison under a vague “law of suspects.” The unleashing of terrorism to silence political opponents imposed order at the cost of freedom. It raised complex moral issues about means and ends and has led to vigorous historical debate: Was the Terror an understandable response to the emergency, one that saved the revolution from a return of the Old Regime, or was it a harbinger of totalitarianism that sacrificed individual life and liberty to an all-powerful state and the abstract goal of regenerating humankind? Finally, the revolutionary government harnessed the explosive force of nationalism. Unified by common institutions and a share of sovereign power, desirous of protecting the gains of revolution, and guided by a national mission to spread the gospel of freedom, patriotic French treated the revolutionary wars as a secular crusade. The combination of a planned economy, the Reign of Terror, and revolutionary nationalism allowed for a full-scale mobilization of resources that drove foreign armies from French soil at the Battle of Fleurus on June 26, 1794.

The revolution’s third phase, the Thermidorian and Directory periods, commenced with the overthrow of Robespierre and the dismantling of the Terror on 9 Thermidor (July 27, 1794) and lasted until the coup d’état on November 9, 1799, that brought Napoléon Bonaparte (1769–1821) to power. A new constitution in 1795 rendered France a liberal republic under a five-man executive called the Directory. The reappearance of property qualifications for political office sought to guarantee the supremacy of the middle classes in politics and to avoid the anarchy that stemmed from popular participation. The seesaw politics of the Directory, which steered a middle course between left-wing radicalism and right-wing royalism, witnessed the annulment of electoral victories by royalists in 1797 and by radicals (Jacobins) in 1798 and undermined faith in the new constitution. Similarly, the regime won enemies with its attacks on Catholic worship while failing to rally educated and propertied elites in support of its policies. Initially, continued military victories by French armies (including those by Napoléon in Italy) buttressed the regime. But the reversal of military fortunes in 1799 and ten years of revolutionary upheaval prompted plotters to revive the constitution in a more authoritarian direction. In Napoléon, the plotters found their man as well as nearly continual warfare until 1815. “Citizens,” he announced, “the Revolution is established on the principles with which it began. It is over.”

The French Revolution is the quintessential revolution in modern history, its radicalism resting on a rejection of the French past and a vision of a new order based on universal rights and legal equality. The slogan “Liberty, Equality, Fraternity, or Death” embodies revolutionaries’ vision for a new world and their commitment to die for the cause. Both aspects of the slogan influenced subsequent struggles for freedom throughout the world, but one might look at the French slave colony of Saint-Domingue for an example. On Saint-Domingue the outbreak of revolution received acclaim by the lower classes among the 30,000 whites, while planters opposed talk of liberty and equality and the destruction of privileges. Revolutionary ideals also quickly spread among the
island’s 30,000 free people of color (affranchis), who, despite owning property and indeed slaves, suffered racial discrimination. Free people of color demanded full civil and political rights after 1789, but the denial of these rights resulted in a rebellion of the affranchis that was brutally repressed. In 1791 Saint-Domingue’s 450,000 slaves commenced the most successful slave revolt in history. Tensions among whites, mixed-race people, and slaves were exacerbated by British and Spanish actions to weaken their French rival, creating chaos on the island. The Convention’s commitment to equality and desire to win the allegiance of rebels resulted in the abolition of slavery in 1794. A later attempt by Napoléon to reinstate bondage on Saint-Domingue failed despite the capture of the ex-slaves’ skilled leader, Toussaint Louverture (c. 1743–1803), and the slave uprising culminated in the creation of an independent Haiti in 1804. Revolutionary principles of liberty and equality had led to national liberation and racial equality.

One also sees the revolution’s significance in the fact that nineteenth-century ideologies traced their origins to the event. Conservatism rejected the radical change and emphasis on reason of the revolution, while liberalism revealed in the ideals of individual liberty and legal (but not social) equality of 1789. Nationalists treated the concept of national sovereignty as a call to awaken from their slumber in divided states or multiethnic empires. Democratic republicans celebrated the radical phase, finding in its democratic politics and concern for the poor a statement of egalitarianism and incipient social democracy. Socialists perceived in the sans culotte phenomenon the rumblings of a working-class movement, while communists considered the Russian Revolution of 1917 the fulfillment of the aborted proletarian revolution of 1792–1794.

For much of the twentieth century Marxist historians understood the revolution as the triumph of a capitalist bourgeoisie and considered it a bloc (in other words, the radical phase of 1792–1794 was necessary to protect the gains of 1789–1791). Revisionists destroyed this view, treating the revolution as the triumph of a new political culture instead of a new social class and whose main outcome was the realization of the absolutist dream of a strong centralized state rather than a complete break with the past. The revisionists’ denial of social class as an important factor in the revolution opened the field to cultural studies and a focus on marginalized groups such as women and slaves. But the revisionist interpretation has failed to achieve consensus, and scholars continue to dispute the revolution’s legacy. According to the neo-democratic view, the declaration of universal human rights, abolition of slavery, and pattern of modern democratic politics give the revolution a foundational place in the struggle for a better world. For revisionists, the violence of the Terror, the destruction of revolutionary wars, the silencing of dissidents and Catholic worshipers, and the formation of a powerful centralized state render the revolution a source of twentieth-century political horrors ranging from nationalist wars to totalitarian regimes.

Students frequently puzzle over the significance of the revolution when, after all, the Bourbons were restored to the French throne after Napoléon’s final exile in 1815. But the restoration never undid the major gains of the revolution, which included the destruction of absolutism, manorialism, legal inequality, and clerical privilege, as well as commitments to representative government, a constitution, and careers open to talent. Once the revolutionary genie announced the principles of national sovereignty, natural rights, freedom, and equality, history has shown that it could not be put back in the bottle.

FREQUENCY DISTRIBUTIONS

Every day, people are confronted with large amounts of information. Occasionally, the amount of data may be so
large that they cannot interpret it in a meaningful way. When this occurs, people often need to organize and summarize the data in such a way that it allows them to uncover patterns or relationships or to use it as tools for analysis and interpretation.

One way to organize large amounts of data is through frequency distributions. A frequency distribution is a summary of data that shows the frequency or number of times a particular observation occurs. To construct a frequency distribution, it is necessary to arrange the data into categories that “represent value ranges of the variables in question” (Fleming 2000, p. 15).

For example, imagine that you are responsible for creating a range of activities for a group of fifty people, and you want to organize the activities according to age. The following is a list of the ages of the individuals in the group:

<table>

The first step in constructing a frequency distribution is to arrange the data from the smallest to the largest value to determine, as in this case, the age range. Next, the different values need to be listed with the number of times a particular age appears—its frequency.

Arranging the data in this way provides people with a more organized way to understand any trends or patterns in the data. However, even after organizing the data based on the frequency distribution, it can still be very overwhelming. By using what researchers refer to as “interval scores” or “class intervals,” frequency distributions become important tools to manage raw data (Hinkley 1982, p. 26). Interval scores or class intervals are intervals that include a range of values. There are several steps to establish class intervals. First, it is necessary to determine the number of non-overlapping classes. Classes need to be mutually exclusive, meaning that a value cannot belong to two different classes at the same time. According to convention, there should be between 5 and 15 classes.

The next step is to decide the width of each class. The size will be the same for all classes, and it is calculated by subtracting the lowest score (4) from the highest score (36) and dividing it by the number of class intervals (e.g., 8). For the previous example, the approximate class width is 5. The larger the width of each class, the smaller the number of classes there will be.

The first step in constructing a frequency distribution is to arrange the data from the smallest to the largest value to determine, as in this case, the age range. Next, the different values need to be listed with the number of times a particular age appears—its frequency.

Arranging the data in this way provides people with a more organized way to understand any trends or patterns in the data. However, even after organizing the data based on the frequency distribution, it can still be very overwhelming. By using what researchers refer to as “interval scores” or “class intervals,” frequency distributions become important tools to manage raw data (Hinkley 1982, p. 26). Interval scores or class intervals are intervals that include a range of values. There are several steps to establish class intervals. First, it is necessary to determine the number of non-overlapping classes. Classes need to be mutually exclusive, meaning that a value cannot belong to two different classes at the same time. According to convention, there should be between 5 and 15 classes.

The next step is to decide the width of each class. The size will be the same for all classes, and it is calculated by subtracting the lowest score (4) from the highest score (36) and dividing it by the number of class intervals (e.g., 8). For the previous example, the approximate class width is 5. The larger the width of each class, the smaller the number of classes there will be.

In addition, one needs to determine the limits of the frequency. The concept of exact limits of a score can be extended to frequency distributions by distinguishing between the exact limits of a given class interval and its score limits. The limits are determined so that each observation belongs to only one class. According to researcher Wiersma Hinkley, “the lower class limit identifies the smallest possible data value assigned to the class. The upper class limit identifies the largest possible data value assigned to the class. The exact limits are 0.5 units below and 0.5 units above the score limits of the class interval”
(1982, p. 27). Consider the age interval 11–15 in Table 2. The interval 11–15 represents the score limits, whereas the interval 10.5–15.5 represents the exact limits. The midpoint will always be the same regardless of what type of limits are used. The midpoint of the interval is defined as “the point on the scale of measurement that is halfway through the interval” (p. 28). There will be scenarios in which some class intervals are empty. When this occurs, researchers suggest that these intervals be eliminated by combining them.

In Table 2, a frequency distribution table is presented as well as the cumulative frequencies. The cumulative frequency is “the total number of scores in the class interval and all intervals below it” (Abrami 2001, p. 63).

In most cases, frequency distributions allow an individual to understand raw data in a more meaningful way. However, it is sometimes necessary to have a visual display of the data beyond numbers to recognize the patterns that otherwise would be difficult to identify. Graphs, when clearly presented, are two-dimensional representations of data that can help in this endeavor. Graphs typically consist of vertical and horizontal dimensions known as axes. By tradition, the horizontal axis is called the abscissa, or the x-axis, and represents the independent variable. The vertical axis is called ordinate, or y-axis, and represents the dependent variable. Histograms, bar graphs, and frequency polygons are graphs that are used to visually display frequency distributions.

HISTOGRAMS

Histograms are one of the most useful graphical representations of statistical data. Histograms display the frequency of an individual score or scores in class intervals by the length of its bars. The majority of histograms represent a single variable. The variable of interest is placed on the x-axis and the frequency distribution, relative frequency, or percent frequency distribution on the y-axis. In histograms, the bars are shown touching one another representing their continuous nature. This means that the variables are interval- (e.g., height or weight) or ratio-scaled. Also, the height of each bar represents its frequency because the class intervals are equal (see Figure 1).

BAR CHARTS

Besides histograms, bar charts are used to visually display frequency distributions. However, contrary to histograms, the variable under study has a nominal and ordinal value, which is represented by the spaces between
each bar. In Figure 2, the specific variables (categories and frequencies) that are used for the classes on each axis are presented.

FREQUENCY POLYGON

Another way to display information is through frequency polygons, also known as frequency curves or line graphs. In this type of graph, the scores of the class interval are displayed by using the midpoint of each class interval. Once these points have been marked, they are connected with straight lines. Frequency polygons are useful when trying to compare two different frequencies in one graph or to highlight trends over time.

Freud, Sigmund

1856–1939

The founder of the intellectual discipline and psychotherapeutic method known as psychoanalysis, Sigmund Freud aimed to “throw light upon the unusual, abnormal, or pathological manifestations of the mind” by tracing them to the psychological forces that produced them (1936, p. 447). The odd manifestations he sought to illuminate ranged from the blatantly strange, such as neurotic symptoms, to deviations from strict rationality found in all people, such as those that occur in dreaming, mental lapses of waking life, such as slips of the tongue, or other special experiences, such as the feeling of “uncanniness.” His inquiries also included ordinary experiences that defied straightforward explanation, such as the capacity of jokes to evoke laughter, and cultural trends that Freud believed exhibited properties of mental life he had identified in individual psychology, such as humans’ susceptibility to religion.

The psychological forces to which Freud traced these phenomena led inevitably, in his view, to childhood. Childhood has the influence it does, Freud maintained, because it affords a unique mode of experience that, on account of its distinctness from later developments of the mind, both produces lasting impressions on people and renders these impressions inaccessible to later consciousness. The most dramatic and best-known consequence of this dynamic is the operation after infancy of unconscious mentation, or ideas and impulses of which people remain unaware that nonetheless influence their behavior. Since the publication in 1900 of The Interpretation of Dreams, Freud's first major treatise on psychoanalysis, Freud's ideas have indelibly altered both popular thought and a wide array of professional disciplines.

THE BIRTH OF PSYCHOANALYSIS

Freud was born in Frieberg, Moravia (now the Czech Republic) on May 6, 1856, and his family moved to Vienna three years later. During the 1890s, as a young doctor collaborating with Viennese physician Josef Breuer, he began treating nervous disorders through the use of a “talking cure,” as he and Breuer called it. The method initially consisted of patients under hypnosis recalling memories associated with their symptoms. This recall, accompanied by the affect connected with the memories, resulted in the elimination of symptoms. An early patient treated in this way, one Anna O., for example, who presented with paralyses and an inability to drink that lacked any organic base, regained her ability to drink when she recalled with disgust a scene from her childhood in which she had discovered her governess's dog drinking from a (human) cup.

On the basis of observations of this kind—reported with Breuer in Studies on Hysteria (1895)—Freud came to believe people are moved in part by mental forces unknown to them. The unconscious, as it came to be known, is composed mostly of thoughts and impressions people pushed from consciousness (or “repressed”) when they were very young. The thoughts and impressions linger in the mind and, unable to discharge, remain on alert for opportunities for expression. When they reach expression, they usually appear in disguise, so as not to elicit fresh repressions. The resulting manifestations include psychopathological symptoms, dreams, lapses of (conscious) speech or action (which Freud called “parapraxes”) such as slips of the tongue, and aspects of character, as well as a variety of ordinary individual and cultural experiences.

BASIC ASSUMPTIONS

Freud's is a general psychological theory that attempts to explain why people think, feel, see, and do as they do. A systematic theory, it contains an integrated body of concepts and propositions from which other concepts and propositions follow. It builds from a small group of first principles, described by Freud as essential constituents of human thought and action that admit of no further reduction and yet account for all conceivable instances of human behavior. Based upon observation and reflection over the course of the forty-plus years spanned by his psychoanalytic writings, Freud eventually changed his ideas about these principles.

Initially, Freud believed all human behavior conforms to what he called the pleasure (or pleasure-unpleasure)
principle. According to the pleasure principle, people always strive to avoid pain and, where possible, attain pleasure. Even behavior that appears inconsistent with this principle, such as the nightmare, must in some way conform to it. Freud theorized in *The Interpretation of Dreams* (1900), for example, that nightmares serve to divert the dreamer from dangerous wishes whose fulfillment would produce frightening consequences. The fearsome content of the nightmare both embodies the dreamer’s perception of danger—such that, on occasion, the dreamer might awaken and thereby terminate the dream—and serves to disguise the wish.

Freud originally conceived the state of pleasure as a reduction in excitation, or tension, on the model of the reflex. Our reflexes, such as the eye-blink or knee-jerk reflex, function to rid the body of stimuli. Thus, at bottom, according to this initial conception, the function of the nervous system is to keep the level of stimulation in the body as low as possible, and pleasure is the consequence of the reduction. As happened with the governing principle itself, Freud changed his view of the nature of pleasure over the course of his writings.

Freud believed that early in their development, in order to survive, humans would have to have formed a reality principle subordinate to the pleasure principle. Although the hallucinated satisfaction of one’s needs, which would constitute the shortest path to their fulfillment, might produce pleasure in the short term, for example, it would lead to ultimate disappointment. Thus, Freud says in his “Formulations Regarding Two Principles in Mental Functioning” (1911), the mind had to “decide” to form a conception of circumstances in the real outer world, so as to be able to alter them and bring about real satisfaction.

Whereas the pleasure principle operates reflexively from birth, the reality principle develops over time in the individual, according to Freud, and likewise developed in the evolution of the species. The reality principle, in turn, would have prompted further developments of the mind, beyond reflexive, or direct wish-fulfilling, functioning. Attention would have given individuals the ability to search their environment for the results of their actions; memory would have given them a means of noting and storing the results; thought would have arisen as a kind of experimental action, allowing individuals to test the (real) consequences of their behavior.

Within the compass of the pleasure/reality principles, Freud distinguished instinct as the driving force of all action. Instinct, as he details in “Instincts and Their Vicissitudes” (1915), is a stimulus to the mind originating within the body that exerts a constant pressure, or “impe tus” toward relief. Because instincts originate within the person and operate at a constant force, rather than originating externally and acting in a single impact, simple reflexive action, such as the withdrawal of the impacted portion of the body, has no effect against the impact. One needs instead to satisfy the instinct. When one’s stomach grinds with hunger, for example, one cannot eliminate the pain by withdrawing one’s stomach from any impinging force. One must eat or be fed. Because instincts require machinations more complicated than reflexive action to be discharged, Freud viewed them as important to the development of the nervous system beyond the primitive reflex.

Freud originally distinguished two classes of instincts, which he believed admit of no further reduction: the sexual instincts and the ego, or self-preservative, instincts. He defined *sexual* broadly, so that it includes, with respect to its physical quality, excitation to any portion of the body, including the skin, for example, as well as the oral, anal, and genital areas.

Psychologically, the sexual instincts subsume the entire field of erotic relations, including those relations “inhibited” in aim, such as friendships and parent-child relations, which entail positive and even excitatory feelings, but not, in the usual course of conscious life, an aim of genital satisfaction. In their most developed manifestation, the sexual instincts serve reproduction. The ego instincts, meanwhile, serve only the individual and have the individual’s safety as their object. In claiming that all human behavior emanates from one or the other of these two classes of instincts, Freud meant that all human impulses and actions remain compatible with one or both fields, not that all human impulses and actions can be reduced to a sex or survival drive. One’s labors on a mathematics problem reduce to a sex or survival drive no more than a sheet of paper reduces to the tree from which the paper was milled. Rather, according to Freud, all of our aspirations and behavior must be traceable in some way to the reflexive bundle from which we arose. The reflexive bundle, in turn, seeks, at bottom, to eliminate the tensions created by its needs, and thus to gain pleasure.

Approximately twenty years after he articulated the pleasure principle, Freud identified an apparent exception to the principle and suggested that a still more basic force operates in the mind. In *Beyond the Pleasure Principle* (1920) he argued that, in contrast with numerous other negative experiences that only appear to contradict the pleasure principle, the traumatic, and more specifically war, neuroses genuinely do so. These neuroses manifest in, among other symptoms, recurrent dreams in which dreamers return to the scene of previous near-death experiences and then awake in a terrible fright. For instance, soldiers returning from war relive attacks in the trenches, and survivors of train wrecks return to the wreck. Each then awakens in terror that no amount of repetition of the dream lessens.
Although Freud could detect no long- or short-term gain in the pattern, he conceded it could embody an attempt at a purpose. Extrapolating from his observation that traumatic neuroses tend to afflict those victims of trauma who did not incur a major injury, Freud surmised that, whereas direct physical insult tends to divert masses of energy to the site of the insult, victims who have escaped injury are left with rampant masses of energy released by the shock of the event. Wholly breached, the psychical system attempts to master the onslaught in retrospect, by generating anxiety that, had it been present during the traumatic event, would have reduced the shock of the event. But after the fact, the attempt serves no purpose. The system neither heals nor learns.

Freud extrapolated from these observations to the existence of a tendency more primordial than the pleasure principle and inherent in all organic life: the compulsion to repeat. The tendency can be witnessed, he believed, in behavior as primitive as the thumb sucking of human babies or the return of schools of fish to the site of previous spawning. In the psyche compromised by the war neuroses, the tendency manifests in a mechanical and almost diabolical repetition of a behavior, in total disregard of its impact upon the person.

From his extrapolation to the repetition compulsion, Freud made the admittedly speculative and far-fetched leap to the idea that all living things seek to return not only to previous states, but ultimately to their original state. Given that all living matter began as inorganic substance, all living things seek to return to an inorganic state; they seek to die.

Freud thus arrived at a new category of instinct, the death instinct, or “Thanatos,” which he conceived as functioning in opposition to the life instincts, or “Eros.” After equivocating briefly on the point, Freud subsumed under the life instincts the two classes of instinct he had originally delineated, the sexual and ego (self-preservative) instincts. Whereas the life instincts, especially as represented by the sexual instincts, seek to unify living matter and create more of it, the death instinct aims to dissolve it.

As Freud originally conceived it, the death instinct denotes the tendency of every living thing to drift toward a state of minimal, and ideally no, excitation. The death instinct of this formulation thus verges on the pleasure principle, according to which pleasure arises with a reduction in stimulation. Freud soon modified his view of the nature of pleasure, however, in a way that lessened this overlap. Although he continued to believe the nervous system functions, at bottom, to rid the organism of tension, and pleasure arises by this means, he acknowledged people’s potential to derive pleasure from an increase in stimulation, as occurs in sexual foreplay, for example. Thenceforth, he distinguished between the Nirvāṇa principle, which expresses organisms’ tendency toward quiescence (and hence the death instinct), and the pleasure principle, which expresses the drive toward pleasure in all its forms, including excitatory ones, and which Freud attributed to the influence of the life instincts.

In the course of Freud’s later works, the death instinct assumes an increasingly active aspect and becomes almost synonymous with aggression. As early as his discussion in *The Ego and the Id*, published three years after *Beyond the Pleasure Principle*, Freud reasoned that individual organisms live long enough to combine with one another, rather than die off, because the death instinct must be neutralized in some way by the life instincts. It is diverted outward over the musculature, he proposed, in the form of aggression, which is eventually directed against others. However, in the wanton destruction he observed in two world wars, Freud perceived an aggressiveness totally divorced from erotic aims, and hence a sign of the ascendancy of something close to a culture of pure death instinct. He concluded the 1931 edition of *Civilization and Its Discontents* with the question of whether Eros would rise again and prevail over humanity.

**CONSEQUENCES OF THE ASSUMPTIONS**

Many of the remaining portions of Freud’s theory follow from the foregoing primitives of mental life and particularly from the pleasure and reality principles, which Freud continued to believe dominate mental life even after he developed the scheme that incorporates the death instinct.

**Meaning and Determinism** One such result is the idea that all behavior, including the most apparently nonsensical, has a reason, or, as Freud says in his *Introductory Lectures on Psychoanalysis* (1917) with respect to psychopathological symptoms in particular, symptoms have a sense. Anna O.’s refusal to drink resulted from her (unconscious) disgust at her governess’s dog, according to Breuer and Freud. Given that people who feel revolted by something normally find it difficult to eat or drink, Anna O.’s behavior followed coherently from its source. Unlike healthy people who refuse food or drink because they feel revolted, however, Anna O. was unaware of both her disgust and its source. Therein lay her pathology. In conceiving dreams as wish fulfillments and parapraxes as products of concealed motives, Freud again followed the assumption that all behavior has a source and a sense. He believed it possible, moreover, for unconsciously motivated behavior, such as dreams, to have not just one source or one meaning, but to be “overdetermined,” having multiple sources and meanings. Thus, for instance, the leering monster in a nightmare might embody both a child’s
anger at a parent and the child's fear of recriminations from the parent.

Freud admitted that some apparently odd behavior arises without apparent motivation. However, he found the occurrence of such behavior improbable. Freud noted in *Five Lectures on Psychoanalysis* (1909) that although some aberrations, such as slips of the tongue, might occur when people operate under fatigue or other stresses, the mistakes cannot be caused by these limitations, because other similar mistakes occur when people are fully attentive (p. 29). Further, precisely because numerous associative pathways lie open and can cause a person accidentally to utter one word instead of another (in the case of slips of the tongue), one needs to explain why a given pathway is chosen on a given occasion.

**Conscious and Unconscious** The separation between conscious and unconscious mental processes arises, according to Freud, primarily through the operation of repression, a reflexive and hence infantile response driven by the pleasure principle, in which individuals withdraw consciousness from painful or frightening impulses in the manner in which one might withdraw one's hand from a hot stove. The pain can be caused either by the clash between impulse in itself and other motives the person may have, or by the individual's anticipation of the external consequences of acting upon the impulse. The repressed impulse, or idea, remains in unconscious memory, sustained by its struggle for expression and at the same time denied that end by the forces that originally led to its repression. In the final chapter of *Totem and Taboo* (1913), Freud postulates a second, smaller category of inherited unconscious ideas. This category includes the most primitive embodiments of the instincts and impulses that, based upon an analysis of modern emotion, he concluded must have been passed along by earlier generations. The latter impulses include guilt for the killing of the primal father and a portion of the hostility that led to the presumed deed.

Freud reserved the term unconscious for these two groups of ideas, repressed unconscious ideas created by individual experience and inherited unconscious ideas, both of which are unavailable to consciousness at the moment and inaccessible to consciousness in general (except with extraordinary effort of the sort embodied by psychoanalysis). As detailed in his 1915 essay “The Unconscious,” Freud distinguished as ‘preconscious’ a separate category of ideas not apprehended by consciousness that, like one's knowledge of one's street address, one can access easily if prompted. Consciousness, within this scheme, is but a characteristic that can attach to mental processes. Freud likened it to a sensory organ that, in this case, illuminates ideation in progress. He attributed to language a primary role in allowing a mental process to become conscious.

Unconscious and conscious ideation exhibit different characteristics, Freud maintained, paralleling the divide between the pleasure principle, which dominates unconscious processes, and the reality principle, which operates only within conscious thought (for purposes of this discussion, preconscious thought is subsumed by conscious thought). Unconscious ideation observes primary process thought, wherein ideas are interconnected associatively one to the next, with no consideration for the whole. One idea may also replace another (“displacement”) and several ideas may converge in a single embodiment (“condensation”). These methods produce dreams, symptoms, and other phenomena, such as jokes, to which Freud ascribed an unconscious contribution. Only conscious ideation incorporates secondary-process thought, which consists of the higher cognitive processes, such as judgment, reasoning, planned action, and the ordering of events in time.

It follows from the properties of the two types of thought that the unconscious admits of blatant contradiction. No feature of unconscious mentation can detect or feel troubled by incoherence. It also knows no denial. Thus, in one's unconscious, one can both love and despise one's mother, or both want freedom from one's parents and want to be constrained and even punished by them. In waking life, normally, one would have difficulty tolerating these ambivalences and would probably repress one pole of the conflict.

**Id, Ego, and Superego** Freud eventually decided that the division of mental qualities into conscious, preconscious, and unconscious did not entirely capture the dynamics of the mind. In particular, unconsciousness appears to attach to mental formations other than those produced by repression that, nonetheless, arise on the basis of experience. In addition to finding their repressed memories elusive, patients undergoing psychoanalysis resist discovering the memories. Other forces in their mind must act to keep the repressed material from consciousness, Freud inferred, and these forces, too, lie outside awareness. Freud labeled these opposing forces as “resistances.”

He developed a new scheme, which he expounds in *The Ego and the Id* (1923), to capture this mental dynamic. He now designated as “id” the portion of the mind containing repressed and inherited unconscious impulses. He defined as “ego” people's efforts to avert danger, whether from internal (i.e., repressed) or external sources, and to maintain their bearings in the environment. The ego includes the resistances and thus has both a conscious and an unconscious portion. Freud designated a third entity, the “superego,” which judges the ego. Although the superego resembles the ego in its judging
role, it shares an unconscious and irrational element with the id, from which it derives.

According to Freud, the superego is the precipitate of the Oedipal complex. The Oedipal conflict, according to Freud, is a normal part of the development of every individual. All children desire more from their parents (or parent surrogates) early in life than the parents can give—at bottom, everyone wants total possession of them. Within this dynamic, children may form a preference for the parent of the opposite sex, although they yearn for both parents and experience the Oedipal conflict with respect to each. Thus, children harbor both love and hostility for each parent. Therefore, as Freud illustrates in Totem and Taboo (1913), ambivalence exists at the core of our emotional life. Eventually, children's desires are frustrated and, in the interest of survival, subjected to repression, with the conflicts embodied by them left unresolved.

The end of the Oedipal period, at around five years of age, prompts individuation from the parents, and consequently their loss. The loss, in turn, prompts children to internalize the parents, which preserves their relationship with them. The internalization is accompanied by an exaggeration of the parents' power, which results from children's earlier repression of their own hostile feelings toward the parents. Emanating now from the internalized parents, the hostile feelings are turned back upon the subject—the child—on whom they discharge more safely than they would have done if the child had unleashed the feelings against the real parents. In exchange, the now browbeaten ego suffers. The entire dynamic, according to Freud, explains much of both psychopathology and the psychology of healthy people.

The Concept of a Person Freud's view of the person is represented by his three schemes for describing the mind. From the perspective of the motivating forces of our action—the pleasure principle and its derivatives—people universally seek, on some level, to avoid pain. In the interest of long-term gain, they may modify their claim to comfort and pleasure in the short term, as Freud discusses in an exegesis on happiness in Civilization and Its Discontents. From the perspective of the division of the mind into conscious (including preconscious) and unconscious, people are ruled by forces both known and unknown to them, and they are thus capable of acts and thoughts both consistent and inconsistent with the traits and values they may (consciously) consider central to their identity. From the perspective of Freud's division of the mind into the dynamic entities of id, ego, and superego, both our behavior and our felt experience are colored by the deeply conflicting forces that confer our humanity upon us: our appetites and our drive for security and survival. In all three views, the person is a compilation of forces, defined by the interaction of dynamic parts. Freud did not distinguish more holistic entities such as the personality or the self.

The Concept of Illness The cause of (neurotic) illness, according to Freud, is unresolved and unconscious conflict, on account of which sufferers retreat into fantasy. Symptoms embody a fulfillment of the fantasies, distorted to escape recognition by the conscious mind. Healthy people struggle with the same conflicts as do neurotic people, and, like neurotic people, they form fantasies to improve upon a sometimes disappointing reality. However, whereas healthy people either find adaptive outlets for their fantasies or indulge them while otherwise going about their business, neurotics' repressed impulses overwhelm their capacity for normal function.

Beginning with his earliest cases, Freud maintained that neurosis is caused specifically by the conflict between sexual and ego drives. Patients' earliest sexual impulses lead to thoughts their self-protective inclinations regard as dangerous, and are thus subject to repression. Although Freud initially believed the forbidden thoughts traced back to actual experiences of seduction, he soon determined, as he noted in his 1909 "Rat Man" case history, that the impression or fantasy of such experiences can alone suffice to initiate pathogenic processes.

Therapy Psychoanalytic therapy presumes that, insofar as repressed complexes (conflicts) cause illness, the path to cure lies in the exposure of the repressed material to consciousness. Repressed complexes have the far-reaching effects they do because the cut-off ideas continue to strive for expression through an increasingly large web of associations. It follows, therefore, that one may recover the instigating ideas by undoing the web of associations. Thus, the “free association” of ideas forms the principal technique of therapy. Beginning with a symptom, dream, or passing thought, patients say whatever comes into their mind in connection with the symptom, and then whatever comes into their mind in connection with the new idea, and so on. Freud believed that all paths lead ultimately to the repressed complex or complexes, so that patients can start with any leading idea to begin to unravel the associative chain or chains.

As their associations veer progressively closer to the material under repression, patients find it increasingly difficult to pursue given lines of thought. Freud believed these experiences of “resistance” form an integral part of the therapeutic process. They provide a window on the forces that are keeping the repressed material hidden and, in becoming manifest, afford patients the means for defeating the forces and allowing the repressed ideas to reach consciousness, where they can be confronted. To
defeat the resistances, patients need to express all associations that occur to them and combat the temptation to block them.

Because of the importance of uncovering and disarming the resistances to the achievement of a lasting cure, Freud abandoned the use of hypnosis in psychoanalysis. Although hypnosis might allow the freeing of repressed content in susceptible patients, in Freud’s experience it led mostly to only short-term cures. Patients’ resistances, still present, rose again and repressed the forbidden thoughts anew. Hypnosis carries the additional disadvantage that not everyone is susceptible to it, whereas the conscious talking cure via free association is open, in principle, to all.

**Development** The development of the mind, in Freud’s conception, follows three broad pathways. The first, within sexual (or as Freud called it, libidinal) development, consists of a progression from autoeroticism, wherein individuals achieve satisfaction diversely from the stimulation of parts of their body, to narcissism, during which individuals, now having gained a unifying seat of experience in the form of the ego, take themselves as the love object, and finally to the phase of (external) object love. Having initially distinguished only autoeroticism and object love as phases in this development, Freud interpolated the phase of narcissism when he found himself otherwise unable to account for the so-called narcissistic disorders of adulthood, such as schizophrenia, in which the ego seems to lose its boundaries. Another development in sexuality encompasses changes in the focus of sexual sensitivity in people from the oral to the anal and, finally, to the genital areas, respectively.

The second trend in development progresses from impulsive toward reflective thought. It is embodied by the development of secondary-process thought, wherein impulses can be inhibited and action tested and planned, and by the gradual replacement of repression by judgment as a means of dispatching painful impressions. It is expressed by the reality principle.

A third trend proceeds from more transparent to more complexly derived, and thus more obscure, behavior. Whereas the dreams of small children often express the unfulfilled (conscious) wishes of the previous day, for example, adults’ dreams contain bizarre and inescrutable (“manifest”) imagery that must be painstakingly unpacked to uncover the instigating (“latent”) dream thoughts. Whereas the motives of children’s sense of humor are clear, adults, who may laugh from similar motives, do not know what they are laughing at. Trends of these kinds arise, Freud believed, from both the separation of conscious and unconscious thought, which makes repression possible, and from the natural “surmounting” (as Freud describes it in his 1919 essay “The Uncanny”) of one developmental stage by another. Regarding the latter process, when one stage succeeds another in development, both the mode of experience embodied by the earlier stage and the experiences accrued in it remain in the psyche. They continue to exert an influence there, though reshaped by the superimposition of later stages.

**THE SCOPE OF FREUD’S WORK**

After incorporating the three previously unlinked fields of dreams, neurotic symptoms, and parapraxes, Freud’s theory came to encompass phenomena as diverse as art, creative writing, the appreciation of beauty, the comic, morality, religion, superstition, the fate of social movements such as communism, and people’s disparagement of the transience of things. In these and other manifestations of human nature, Freud not only perceived the operation of unconscious thought, the contribution for which he is most widely known, but also speculated provocatively about the nature of phenomena that otherwise elude explanation. His commentary exposes the elusiveness.

Freud’s account of the comic in *Jokes and Their Relation to the Unconscious* (1905), for instance, emphasizes the need for investigation to penetrate beyond the necessary and sufficient conditions of what makes something funny to the question of why laughing is what people do when an event meets these conditions. His brief remarks on beauty in *Civilization and Its Discontents* show the need for theory to reach beyond the delineation of the attributes of beautiful things to an account that explains the feeling that accompanies people’s perception of beauty. In his extensive, though scattered, treatment of morality, he labors to account for the compulsiveness of morality and the feelings that accompany moral sensibility, such as moral righteousness and moral indignation, as well as the scope and nature of moral rules.

In his short essay “On Transience” (1916), Freud both awakens the reader to the possibility that one could appreciate things more, rather than less, on account of their transience (for instance, they could better appreciate the beauty of spring because it will disappear), and provides an explanation of the common tendency instead toward the disparagement of transience. With respect to communism, which he considers in a longer discussion of the problem of aggression in society in *Civilization and Its Discontents*, Freud, who reserved judgment on the economic claims of the system, suggested its psychological premises are untenable. He believed that when human aggression is deprived of one of its essential tools, namely material property, it will find other outlets. In all of these and in other areas, Freud opened lines of inquiry that remain interesting and novel. Because of its vast reach and systematic base, Freud’s theory has profoundly influenced disciplines throughout the social sciences and humanities,
as well as the arts. It has shaped the way human nature is viewed by scholar, practitioner, and layperson.

CRITICISM OF FREUD’S THEORY
Freud’s theory has been challenged since its inception, initially for its stipulation of unconscious mentation altogether, and later for its claims regarding the nature and influence of unconscious thought. Many believe Freud overinterpreted behavior. Experimental psychologists such as J. Allan Hobson and Daniel Schacter, for instance, maintain that parapraxes and dreams, respectively, may arise from normal features of cognitive process and brain function, rather than from unconscious motives. Likewise, critics suggest neurotic symptoms may reflect relatively superficial adaptations to faulty wiring or chemical imbalance, rather than deep-seated conflict.

Adolf Grünbaum and other commentators have questioned Freud’s characterization of psychoanalysis as a science on the grounds that the theory is not testable. For a theory to be testable, one needs to conceive limiting cases with respect to which the theory could be proved wrong, according to these authors. However, they continue, one cannot refute the claim that neurotic symptoms express repressed complexes or that dreams fulfill wishes (the dreams of traumatic neurosis, which Freud excepted, notwithstanding), because any given symptom might express a repressed complex and any given dream might fulfill a wish. One simply may not have uncovered the hidden material. It goes without saying that Freud’s more speculative claims, such as his stipulation of a death instinct, are dismissed by critical and even supportive discourse altogether. Psychoanalysis, as a means of cure, has been variously assailed as ineffective, subject to suggestion and, by the analyst, and unnecessarily costly to patients. In its standard form it involves multiple sessions per week and a highly trained practitioner.

Theorists who followed Freud, including his own disciples, subsequently modified his theory and the practice of psychoanalysis. Some, such as Carl Jung, reconceived the nature of the unconscious, while others, such as Melanie Klein, replaced drives or instincts with interpersonal (“object”) relations as the pivot of the psyche. Others, such as Alfred Adler, placed relatively greater emphasis than Freud did on the ego, while lessening the emphasis on the sexual drives. In Freud’s wake, many varieties of talking therapy were created, some ultimately with little connection to the tenets of psychoanalysis, save the notion that people’s ways of thinking about their lives, cultivated by their previous experience, may taint their happiness more than do the external events that befall them. Diverse therapies also share the belief that giving expression to one’s concerns may both begin to lift the burden they impose and promote self-enlightenment.

Freud died on September 23, 1939, in England, where he lived for the last year of his life. The cause was mouth cancer, which had plagued him for many years. Since then, the controversies over the credibility of his theory and the promise of psychoanalytic treatment have continued. Regarding treatment, Freud established as an ideal the absence of suggestion, as Jonathan Lear notes. Conducted appropriately, psychoanalytic therapy has met with modest success. At the same time, no other type of therapy has proved universally effective. Regarding the credibility of the theory, Freud himself addressed many of the concerns raised by both his contemporary and subsequent critics. In numerous writings, for instance, he reviewed and rejected face-value accounts of the phenomena he addressed, and he made comparative assessments of the plausibility of competing psychoanalytic interpretations of behavior. In these exercises, he extrapolated to the predictions of competing claims and assessed their plausibility, given the data, as would befit any exercise in hypothesis-testing. He also stated, with respect to some claims, that he was following out the logic of an idea, rather than asserting testable claims. He claimed this, for instance, in the often-dismissed Beyond the Pleasure Principle (1920), regarding his ideas about the death instinct. Although it remains to be seen whether evidence and logic require hypotheses in the direction of Freud’s tenets, it is difficult to identify alternative theories that address, let alone attempt to explain, the quintessentially human phenomena Freud took as his central object.

PRIMARY WORKS

Friedan, Betty

1921–2006

Betty Friedan was a catalyst in the development of the women's movement in the United States in the 1960s. In 1963 her book *The Feminine Mystique* was published, and it provided a clarion call to women—especially suburban housewives—to move beyond their lives in the home and to actively pursue careers as well as social and political equality. Several decades later, the book had sold more than three million copies.

The daughter of a Russian immigrant who owned a successful jewelry store in Peoria, Illinois, and a mother who gave up a newspaper career to raise her children, Bettye (as she was named at birth) attended Smith College, graduating with honors in 1942. After earning her bachelor's degree, she dropped the “e” in her first name and attended the University of California, Berkeley, to pursue a graduate degree in psychology. She left the university in response to pressure from a boyfriend, eventually moving to New York, where she began writing for labor newspapers. She married Carl Friedan in 1947 (they divorced in 1969), and they moved to the suburbs of New York City, where she raised three children (Daniel, Emily, and Jonathan).

In preparation for her fifteenth college reunion, Friedan surveyed her classmates and discovered a vague but poignant dissatisfaction with their seemingly pleasant suburban lives. She extended her survey to alumna of other women's colleges and also interviewed numerous women; the results of her investigation provided the basis for *The Feminine Mystique*. The book galvanized women across the nation, particularly white women, and Friedan entered the national spotlight as an assertive spokesperson. In 1966 she was one of the founders of the National Organization for Women (NOW), serving as its first president, a position she held until 1970. NOW provided women with a national platform to discuss their concerns, to advocate for political rights, and to engage in social and political activism. In 1969 Friedan was one of the founders of NARAL Pro-Choice America, an organization that advocates for abortion rights, and in 1971 she helped to found the National Women's Political Caucus.

Friedan authored six subsequent books, the last of which was a memoir. In her later books, she began to advocate for a broad movement for the working class, people of color, and gays and lesbians. She was a visiting professor at Columbia University, Temple University, and the University of Southern California. In the years just before her death, she worked with the Institute for Women and Work at Cornell University.

*The Feminine Mystique* remains a highly influential book, although much of its argument, focused on conditions in the 1960s, is now the source for more recent forms of feminism, and thus it is ironically both essential reading and dated. While her unflagging efforts on behalf of women focused attention on gender disparities, she...
achieved notoriety in the women’s movement by calling lesbian feminists “the lavender menace” because they provided an easy target for critics who prophesied the demise of the family. Although The Feminine Mystique was focused on the conditions of suburban mothers, one of her cofounders of the National Women’s Political Caucus, Fannie Lou Hamer (1917–1977), was a key African American activist in the long and bitter struggle for civil rights in Mississippi and political recognition in the national Democratic Party.

The first extensively organized effort for women’s rights occurred in the 1800s and early 1900s when women fought for the right to vote. Betty Friedan was an architect of the second organized effort in the 1960s.

FRIEDMAN, MILTON
1912–2006

Milton Friedman is best known for his influential contributions to monetary macroeconomics and for his strong advocacy of the role of free markets in solving social problems. The son of poor Jewish immigrants in New York City, Friedman was educated under a scholarship at Rutgers University, where his main influences were Arthur F. Burns and Homer Jones. Upon graduation in 1932 with a joint major in economics and mathematics, he was offered a tuition scholarship in economics at the University of Chicago, where he was a student of Frank Knight and Jacob Viner, among others. After an academic year in Chicago, Friedman received a fellowship to move to Columbia University, where he was taught by Harold Hotelling and Wesley C. Mitchell. In his third year as a graduate student he returned to Chicago as research assistant to Henry Schultz. Apart from an academic year as visiting professor at the University of Wisconsin (1940–1941), between 1935 and 1945 Friedman worked in Washington, D.C., and New York for the National Resources Institute (1935–1937), the National Bureau of Economic Research (NBER, 1937–1940), the Treasury Department (1941–1943), and the War Research Division of Columbia University (1943–1945). His Columbia doctoral dissertation was concluded at the NBER by 1940 as part of collaboration with Simon Kuznets on incomes from independent professional practice. However, its publication and Friedman’s PhD were delayed until 1945 and 1946, respectively, because of a controversial result about the effect of monopoly powers on physicians’ income. After a year as associate professor at the University of Minnesota, Friedman joined the faculty at the University of Chicago in 1946, replacing Viner as professor of economic theory. He became full professor in 1948, the same year he rejoined the NBER to carry out (together with Anna Schwartz) study of monetary factors in business cycles, a project that culminated with the Friedman-Schwartz 1982 volume Monetary Trends in the United States and the United Kingdom. Friedman continued to teach at Chicago until 1977, when he took up a position as senior research fellow at the Hoover Institution at Stanford University. In 1951 he received from the American Economic Association the John Bates Clark Medal, and in 1976 was awarded the Nobel Memorial Prize in economics.

CONSUMPTION AND UTILITY

Friedman’s early contributions grew out of his statistical research of incomes and consumer expenditures carried out in the 1930s; these include the development in 1937 of a nonparametric significance test for ranked data, and the research that led to his 1945 book with Kuznets. That book introduced the concepts of permanent and transitory income, which would be the focal point of Friedman’s 1957 econometric exercise in the Theory of Consumption Function. Friedman’s hypothesis that permanent aggregate consumption is a function of permanent (in the sense of long-term expected) income was a solution to Kuznets’s empirical findings that, contrary to prevailing Keynesian models at the time, the average propensity to consume does not decline with rising income. The permanent income hypothesis has had a profound impact on empirical work on the consumption function and other fields, despite its implicit treatment of lifetime as infinite, which makes it unsuitable to deal with optimization over the expected life of the economic agent. It was a crucial element of Friedman’s overall attack on Keynesian economics because it implied (1) strong criticism of the so-called Keynes-Hansen secular stagnation thesis (which depends on the assumption of a rising saving-income ratio); (2) rejection of Keynesian unemployment equilibrium, on the basis of the introduction of wealth into the consumption function and by that of the...
positive effect of price reduction on consumers’ expenditure; and (3) dismissal of the assumption that consumption is a stable function of current income, which undermined the stability of the Keynesian multiplier. Another important contribution by Friedman to the pure theory of statistics and decision-making was his 1948 essay (with Leonard Savage) on the implications of the von Neumann-Morgenstern cardinal utility function for risky choices, which influenced the development of portfolio selection theory. Friedman and Savage showed that choice under uncertainty could be represented by a process of maximizing expected utility, which allowed them to explain the simultaneous practice of gamble and insurance under some assumptions.

QUANTITY THEORY OF MONEY

Although monetary theory and policy had attracted Friedman’s attention since his discussion of the inflationary gap at the Treasury Department in the early 1940s, it was only after the 1950s that money became the main topic of his research agenda, especially with the start of the Chicago Workshop on Money and Banking, set up by him in 1951. The first product of that workshop was the 1956 volume of Studies in the Quantity Theory of Money, edited by Friedman. The book opened with his “restatement” of the quantity theory as a proposition about the empirical stability of the demand for real money balances in relation to a few arguments, including income. Friedman’s claim that his approach to money demand— as the outcome of the agents’ portfolio decision about how to allocate their wealth among alternative assets— was in tune with the Chicago quantity theory tradition was challenged, however, by Don Patinkin and other commentators. In any event, Friedman’s point that the velocity of circulation of money is determined mainly by changes in real income represented an alternative to the prevailing Keynesian income-expenditure mechanism based on the stability of the investment multiplier. It led to Friedman’s proposition that substantial changes in prices or nominal incomes are the result of changes in the nominal supply of money. The empirical investigation of that claim was the object of Friedman and Schwartz’s Monetary History (1963), the first of their books for the NBER. That book is the most important contribution to the “monetarist” approach to the business cycle, and it followed the NBER founder Wesley Mitchell’s practice of extracting cycles and trends from detailed time series. It is also congruent with Friedman’s emphasis on testing the empirical implications of theories, worked out in his influential 1953 essay on the methodology of positive economics. Friedman and Schwartz examined individual episodes in U.S. monetary history to establish the determining causal influence of changes in money stock on prices and economic activity. In particular, they put forward an explanation of the Great Depression (1929–1933), alternative to the Keynesian one, as the consequence of inept policy responses by the Federal Reserve to the contraction in money supply brought about by bank failures and rising currency/deposit and reserve/deposit ratios.

NATURAL RATE OF UNEMPLOYMENT

Apart from the primacy of exogenous monetary impulses, another main element of Friedman’s monetary economics is the stress on the role of expectations in the transmission of monetary changes to nominal and real variables. Although the theme of expectations already could be found in his writings in the 1950s and early 1960s, it was only after his 1967 seminal presidential address to the American Economic Association that the distinction between expected and unexpected values of variables became prominent. Friedman argued that the trade-off between inflation and unemployment measured by the traditional Phillips curve is a temporary phenomenon that disappears in the long run, once inflation becomes anticipated by economic agents (1968). Friedman coined the phrase natural rate of unemployment to express the notion that monetary authorities are only able to keep the current unemployment rate below its long-term equilibrium level if inflation is accelerating—the “natural rate” is the rate of unemployment (determined by real factors such as labor mobility, etc.) at which inflation is nonaccelerating and agents’ expectations about the value of real variables (such as real wages) are fulfilled. In contrast with his other contributions to monetary economics, the natural rate of unemployment hypothesis was not subjected to empirical testing by Friedman, in part because his definition of the concept is not fully operational, as argued by Frank Hahn and others. As it happens, some key elements of Friedman’s 1967 address could be found already in David Champernowne’s 1936 critical reactions to J. M. Keynes’s General Theory. The real wage rate that workers would demand if they forecast future prices correctly was called the basic real wage by Champernowne, and the corresponding unemployment level was termed the basic unemployment rate, just like Friedman’s natural rate. According to Champernowne, the rate of price change will accelerate if actual unemployment differs from its “basic” value, which will bring it back to its long-run value through the effect of inflation (or deflation) acceleration on the setting of the interest rate by monetary authorities.

MONEY GROWTH RULE

The implications of Friedman’s theoretical and empirical monetary studies for the operation of monetary policy were worked out in his 1959 Program for Monetary
Stability and in essays collected in 1969. One of his main empirical findings was that monetary changes affect output and prices with a long, variable, and unpredictable lag; this is behind his skepticism of the stabilizing role of discretionary monetary policy. Instead, Friedman argued—coherently with the Chicago tradition of Henry Simons and others—for a fixed rule to expand the money supply by a constant and known annual percentage. As Friedman was aware, such a rule could only be implemented with a system of flexible exchange rates, which had been advocated by him since the early 1950s on the grounds that flexible rates would lead to a more efficient process of adjustment of the balance of payments. At first, Friedman suggested that the rate of growth of money supply should aim at the stabilization of the price level (around 4%), but he later claimed that, from a purely economic-welfare perspective, the optimal money stock should grow at such a rate (around 2%) to bring about a rate of deflation equal to the rate of return of real capital. This would mean, in long-run equilibrium, that the private marginal cost of holding real cash balances (the nominal rate of interest) is the same as its social marginal cost (zero), a Pareto optimum situation. Whereas Friedman’s notion of an optimum money supply was primarily of theoretical interest, his more general point—that the main feature of the money growth rule is not the growth rate itself but the adoption of some fixed rate that would produce some known and steady moderate inflation or deflation—has influenced central banks, especially in the monetarist experiments carried out between 1979 and 1982 in the United States and during Margaret Thatcher’s premiership in the United Kingdom. Those experiments and their results were highly contented, however, as a result of the instability of the demand for money following financial deregulation and the weak link between money growth and inflation in the 1980s. Moreover, the publication of Friedman’s last important work on money at about that time (Friedman and Schwartz 1982) raised strong criticism of their empirical analysis of the relation between money, income, and prices in the United Kingdom (Hendry and Ericsson 1991).

INFLUENCE AND CRITICAL REACTIONS

Despite the intense controversies that surrounded Friedman’s monetary economics in the 1960s and 1970s—especially the criticism by James Tobin and others that he had not succeeded in specifying the mechanism of transmission from money to output and prices (Gordon 1974)—it is true that many of his propositions became by the end of the twentieth century part and parcel of macroeconomic theory and policy, even if they are not always explicitly associated with his name. These include the notion that monetary policy should target nominal quantities (such as inflation) instead of output and employment, as well as the view that it is usually a more potent tool for economic stabilization than fiscal policy. It is worth noting that although Friedman’s emphasis on the role of the market and limits to state intervention in the economy, plus his rejection of activist macroeconomic policies, are shared with “Austrian economics” (theories espoused by, for example, Friedrich von Hayek, Ludwig von Mises, and Murray Rothbard), his relationship with that group of economists has been difficult. Friedman’s restatement of the quantity theory of money approach to monetary economics was partly motivated by his perception that, in contrast with the Chicago tradition of Simons, Viner, and others, Austrian economists (called “London School” by Friedman) are mistaken in their argument that depressions should not be avoided because they are the inevitable result of the prior boom. For their part, the Austrian economists have criticized Friedman’s monetary economics for overlooking the role of intertemporal coordination failures and relative price changes in the business-cycle mechanism. They have also rejected Friedman’s credential as the leader of free-market economics because, in their view, some of Friedman’s proposals—such as the maintenance of government control over the money supply, state support of education by vouchers redeemable at private schools, guaranteed annual income through a negative income tax—indicate that he has intended to make the state more efficient, rather than just to remove it from the economic realm.

FRIENDSHIP

Friendships are enormously important in the lives of most people. Having good, mutually responsive friendships has been associated with better physical and mental health, higher self-esteem, and greater feelings of self-worth.

NATURE OF FRIENDSHIPS

What are friendships? Different researchers have emphasized features such as loyalty, trust, voluntary interdependence, proximity-seeking, and idiosyncratically thinking about and responding to one another. All these features are important, but most significant is the fact that friendships are normatively characterized by adherence to a communal norm. That is, friends are expected to be mutually responsive to one another’s welfare by providing help, supporting one another’s goal strivings, and including one another in enjoyable activities. Importantly, such responsiveness ought to be given voluntarily and it should occur on a noncontingent rather than a tit-for-tat basis. Indeed, research has demonstrated that observers are more likely to infer friendship when people give and accept noncomparable rather than comparable benefits, and when they split restaurant bills evenly rather than according to exactly who has ordered what.

Other relationships besides friendships also are normatively communal—romantic or spousal, parent-child, and sibling relationships. What, then, distinguishes friendships from these other relationships? We contend that friendships are communal relationships that also are nonexclusive, nonfamilial, and normatively nonsexual (although research indicates that some people engage in sexual contact with others whom they consider to be “just friends”). Friendships also are different in that there are no strong social prescriptions, legal obligations, or mutual investments holding them together. Interdependence theory therefore suggests that commitment in friendships is more voluntary than in other types of communal relationships, and that friendships may both form and fade with less fanfare than other communal relationships.

Whom do people choose as friends? Researchers have studied this topic extensively and have found several reliable predictors of friendship. For both children and adults, functional propinquity, or likelihood of mutual contact, is a basic and potent predictor of friendship choice. People
simply have more opportunities to develop friendships with others whom they encounter regularly. According to the similarity-attraction principle, similarity is another powerful predictor of friendship. Indeed, research offers considerable support for the maxim, “birds of a feather flock together.” People like others who are similar to them in terms of attitudes, values, race, and socioeconomic status. This may be because it is reinforcing to interact with others who agree with them, and because there is an increased likelihood of contact among those who are similar. Relevant to the former possibility, recent research has shown that people are especially likely to feel close to others with whom they share a negative attitude about another person. Relevant to the latter, research suggests that students in racially diverse schools are more likely to have cross-race friendships than those from more homogenous schools. One additional predictor of friendship is assumed reciprocity of liking. Both children and adults like others whom they think like them.

There is also some evidence for the maxim that “opposites attract.” For example, self-evaluation maintenance theory suggests that people feel most comfortable with and find it easiest to be communally responsive to peers who excel in performance domains that are distinct from those domains about which they themselves care, and within which they themselves excel.

DIFFERENCES IN FRIENDSHIPS

Developmental research has emphasized the notion that friendship changes across the lifespan. Young children define friends as people with whom they spend time and engage in joint activities. For them, a primary goal of friendship is spending play time together. Older children begin to define friends based on interpersonally relevant traits and behaviors. To adolescents and adults, intimacy and self-disclosure are defining features of friendship, and a primary goal of friendship is meaningful conversation.

Researchers have long been interested in sex differences in friendship. Many have argued that female-female friendships are more intimate than male-male friendships. This was considered a truism for quite some time, and there is evidence to support this idea. Female friends talk with one another more than do male friends, and male friends perform joint activities with one another more than do female friends. Furthermore, when men do talk in their friendships, there is a greater tendency for their conversational topics to revolve around activities. Women, in contrast, tend to share feelings more directly and to talk more explicitly about their relationships. Several studies indicate that male-female friendships are more similar to female-female than male-male friendships, however. So, men might rely more on female than male friends for self-disclosure and intimacy. The idea that men's friendships are less intimate is no longer uncontroversial, however. Several researchers have pointed out that the very definition of intimacy might be different for men and women. Others have raised the question of whether men are incapable of being more intimate, choose to be less intimate, or achieve intimacy through means other than self-disclosure. No matter whose relationships are most intimate, recent research has suggested that both men and women identify intimacy as a central component of friendship. Some research also suggests that women engage in joint activities and men self-disclose more than earlier evidence indicated. It may be the case that any differences between male and female friendships are matters of degree rather than qualitative differences.

As stated earlier, people are more likely to befriend members of their own racial and ethnic groups. Once friendships are formed between people from different racial or ethnic groups, there is a tendency for these friends to engage in fewer shared activities than same-race or same-ethnicity friends. The types of activities in which people engage are similar regardless of racial composition, however. Like sex differences, race differences in friendship may be more quantitative than qualitative.

Considering the importance of friendships for everyday life, one could argue that the topic is underrepresented in the social scientific literature. This is particularly true of the literature on adult relationships, which tends to emphasize romantic relationships. Research on children and adolescents, however, has placed a comparatively greater emphasis on friendships. Fortunately, the adult literature has begun to catch up in recent years. The future holds a number of exciting possibilities for research on friendship. In addition to continuing to elucidate basic friendship processes, researchers are increasingly investigating issues such as cross-cultural differences in friendships, the nature of long-distance friendships, and the nature of friendships formed in an online context or “e-friendships.”

Margaret S. Clark
FRISCH, RAGNAR
1895–1973

The Norwegian economist Ragnar Frisch was a dominant force in the development of economics during the interwar period of the 1920s and 1930s. He pioneered the use of quantitative methods encompassing three fields of analysis: economic theory, mathematics, and statistics. Economists drew on these three areas to develop the specialized field of econometrics. Frisch continued to build this field of study after World War II (1939–1945) until his death in 1973. He was honored in 1969 with the Nobel Prize in Economics, which he received jointly with Jan Tinbergen (1903–1994) of the Netherlands, who was also a European pioneer in the field of econometrics.

Frisch’s main contributions were in developing statistical and mathematical analysis of several branches of economics. He estimated production and demand relationships, theoretical mathematical models of economic cycles, and systems of international trade. Together with Joseph Schumpeter (1883–1950) of Harvard, Irving Fisher (1867–1947) of Yale, and many other leading scholars from Europe and the United States, Frisch influenced Alfred Cowles (1891–1984) to help finance the launching in 1930 of the Econometric Society and in 1933 of its journal, *Econometrica*, which was to become a leading scholarly publication. The Econometric Society remains a strong international force in many branches of economics.

Tinbergen’s statistical models of the dynamic fluctuations of national or world economies constitute one path of econometric research that flourishes today, and Frisch’s theoretical economic models, statistical archives, and estimation methods form a different path for understanding the working of economic systems. Frisch’s model was, at an early stage, called an *ecocirc* system. It expanded a line of thinking that grew out of his celebrated article “Propagation Problems and Impulse Problems in Dynamic Economics” (1933), which shows how continuing external random shocks to an economy can propagate regular, maintained cycles that could otherwise fade away.

Students of Frisch became important in Norwegian and international organizations and institutions. Trygve Haavelmo (1911–1999), a favored student of Frisch, became a Nobel laureate in 1983. During the Great Depression, Frisch delivered radio addresses and published articles on economic policies to improve the Norwegian economy. His recommendations anticipated some of the proposals made by John Maynard Keynes (1883–1946) for the United Kingdom, the United States, and other European economies.

During World War II, Frisch was imprisoned in a German-controlled camp, Grini, where many intellectuals and senior Norwegian officials were held. Soon after his release, he visited the Cowles Commission at the University of Chicago, where Haavelmo and others were actively engaged in econometric analysis using many of Frisch’s ideas. Frisch turned his attention in the postwar years not only to Norwegian and international economic systems, but also to economic development problems of comparatively poor countries. During this time he visited India, where he interacted with Indian economists and political leaders. Frisch continued to work on his ecocirc system, training Norwegian students and colleagues to deal with expanded subsystems for an enlarged master plan, but he did not complete his overall project—to build a complete economic accounting and planning system. In a larger framework, after World War II, he was inspired by the input-output analysis of Wassily Leontief (1906–1999), the social accounting systems of Richard Stone (1913–1991), and international trade matrices developed at the United Nations, where he consulted on applied economic analysis. Frisch also maintained a deep interest in bee populations and felt that the development of bees and their products was helpful in understanding the economic development of human populations. He was proud of their fine honey output as well.

FROMM, ERICH
1900–1980

Born in Frankfurt, Germany, in 1900, Erich Fromm was affiliated with the Institute for Social Research, later known as the “Frankfurt school,” from 1928 to 1938. Trained in psychoanalysis, Fromm combined Freudian psychology with Marxian social theory. In his early essays he indicates the common dialectical and materialist elements in Marx and Freud and applies his Marxian social psychology to interpret such phenomena as religion, the sadomasochistic roots of the authoritarian personality, and the dominant bourgeois character types.

Forced to flee from Nazi Germany in 1933, Fromm settled in the United States and lectured at the New School of Social Research, Columbia University, Yale University, and Bennington College. In the late 1930s Fromm broke with the Institute of Social Research, and with *Escape from Freedom* (1941) he began publishing a series of books that won him a large audience in the United States and eventually throughout the world.

*Escape from Freedom* argued that alienation from soil and community in the transition from feudalism to capitalism increased insecurity and fear. Documenting some of the strains and crises of individualism, Fromm attempted to explain how alienated individuals seek gratification and security from social orders such as fascism. Protestantism, with its emphasis on individual salvation and damnation, increased individuals’ fears and made them susceptible, he argued, to manipulation by social forces. Moreover, capitalism, with its emphasis on individual gain and harsh market competition, which mediated success and failure, also contributed to feelings of insecurity. Migrations from country to towns and factories, central to industrial modernity, created a new urban civilization that increased individuals’ feelings of rootlessness and alienation.

In the late 1930s Fromm broke with the Frankfurt school, in part over his interpretation of Freud and in part over personality conflicts with key members such as Theodor Adorno (1903–1969) and Herbert Marcuse (1898–1979). Henceforth, Fromm went his own way, often appearing as a prophet in the desert of American affluence and consumerism as he attacked the “marketing orientation,” the bourgeois proclivity to privilege having over being, and indeed the entire American system of institutions and values.

His post–World War II books, *Man for Himself* (1947) and *The Sane Society* (1955), applied Fromm’s Freudian-Marxian perspectives to sharp critiques of contemporary capitalism. Fromm popularized the neo-Marxian critiques of the media and consumer society, and promoted democratic socialist perspectives during an era when social repression made it difficult and dangerous to advocate radical positions. Although his social critique was similar in many ways to that of his former colleague Marcuse, the two thinkers engaged in sharp polemics from the mid-1950s into the 1970s. Marcuse began the polemic by attacking Fromm as a neo-Freudian revisionist (Marcuse 1955, p. 238), and Fromm retaliated by calling Marcuse a “nihilist” and “utopian” (Fromm 1970, p. 62).

Marcuse claimed that Fromm’s emphasis on the “productive character” simply reproduced the “productivism” intrinsic to capitalism, and that his celebration of the values of love, in books such as *The Art of Loving* (1957), and religion simply reproduced dominant idealist ideologies (Marcuse 1955, p. 258).

Fromm was a prolific writer up until his death in 1980, publishing a series of books promoting and developing Marxian and Freudian ideas. He was also politically active, helping to organize the National Committee for a Sane Nuclear Policy in 1957 and engaging in early “ban the bomb” campaigns, as well as participating in the U.S. antiwar movement of the 1960s. Fromm continued to argue for a humanistic and democratic socialist position, and claimed that such elements were intrinsic in Marxism. His many books and articles had some influence on the New Left and continue to be read and discussed today.

FULL CAPACITY

Full capacity refers to the potential output that could be produced with installed equipment within a specified period of time. Actual capacity output can vary within two limits: (1) an upper limit that refers to the engineering capacity—that is, the level of output that could be produced when the installed equipment is used to its maximum time of operation and maximum technical efficiency; and (2) a lower limit identified with the scrapping of plant and equipment—that is, the level of output that is no longer profitable to produce. By full (or normal) capacity at the microeconomic level, economists refer to the level of output that corresponds to minimum cost production, usually identified with the minimum point of a usual U-shaped average cost curve. Before this point, we have economies of scale that firms would be willing to take advantage of by expanding their output. Past this point, firms encounter diseconomies of scale that they would like to avoid by cutting down their level of production. The problem with this definition is that such a minimum point is hard to identify empirically. Furthermore, the average cost curves in manufacturing are usually characterized by constant returns to scale for fairly large variations in the output produced, and so full (normal) capacity is identified with the level of output past which the firm considers the installment of a new plant. Consequently, normal output is conceived differently in the various schools of economic thought.

Starting with the classical economists, full or normal capacity is identified with the level of output where the forces of demand and supply are equal and the production technique along with the distributive variables (i.e., the real wage and the rate of profit) are taken as givens. Hence, normal capacity is different from engineering capacity in the sense that it takes into account economic considerations. Consequently, normal or full capacity will equal a certain percentage of maximum engineering capacity simply because it does not pay to use the plant and equipment past this percentage point, even though engineering-wise such a use would be possible. It is important to point out that full capacity in classical economics is restricted to capital. The idea is that the purpose of production is the extraction of profits as an end in itself, so the primary concern of entrepreneurs is the full employment of their capital, while labor simply adjusts to the requirements of capital regardless of the level of unemployment. In short, full capacity may be accompanied by considerable unemployment of labor.

For neoclassical economists, full capacity is identified with both the full employment of capital and the full employment of labor. Full capacity is expected to prevail in the economy in the long run, and any deviations from full capacity are attributed to external economic shocks that may displace the actual output away from the full capacity output. However, neoclassical economics claims that if the price mechanism works freely it is expected that sooner rather than later the actual level of output will be restored back to its optimal level.

A characteristically different view was propounded by John Maynard Keynes (1883–1946), who argued that the unemployment of capital may coexist with the unemployment of labor, precisely because of the failure of the market system to generate effective demand sufficient to fully employ all the factors of production. Keynes further argued that once the economy finds itself in such a situation it stays there, since aggregate demand and aggregate supply are equal to each other. Output and therefore employment of both capital and labor can change through variations in aggregate demand induced by government intervention, and in this way the economy may reach a point that is consistent with the full capacity of both capital and labor. In the Keynesian perspective, prices do not play a role because of the assumption of constant returns to scale.

Modern macroeconomic approaches envisioned a novel concept of full capacity identified with the level of output at which there are no pressures for the acceleration or the deceleration of the inflation rate. Furthermore, the rate of capacity utilization defined as the ratio of actual output to the full capacity output has established, at least for the U.S. and Canadian economies, a benchmark capacity utilization rate that is consistent with a stable inflation rate. This concept came to be known with the acronym NAICU, that is, the nonaccelerating inflation capacity utilization rate, which is supposed to be more general than the currently more popular nonaccelerating inflation rate of unemployment known as the NAIRU, which is restricted to the employment of labor alone. Full capacity output is identified on the basis of survey measures for the U.S. and Canadian economies and is associated with a rate of capacity utilization approximately equal to 82 percent of potential output. The empirical evidence for the years before the mid-1990s has been supportive of this hypothesis for both the U.S. and the Canadian economies, but this hypothesis lost part of its explanatory force in the post-1990 years. These rather negative results raised doubts about the official measurement of potential output based on surveys, and encouraged research in the development of alternative measures of the full capacity output.

There are various methods for the estimation of potential output that can be distinguished between those
based on economic theory and those that are not. Economic measures include those derived from the use of production or cost functions. More recently, there have been measures developed based on the use of econometric techniques such as the cointegration and the structural vector autoregressive models. Noneconomic measures include various statistical methods starting from peak-to-peak measures of capacity output to simple moving averages and sophisticated filtering techniques. Finally, among the atheoretic measures of capacity output, the approach based on surveys is the most popular and is conducted in many countries. The survey measures of capacity output of the U.S. Federal Reserve Board is the oldest one and is based on a nationwide survey where the managers of manufacturing firms are asked to identify “the maximum level of production that their establishment could reasonably expect to attain under normal and realistic operating conditions, fully utilizing the machinery and equipment in place.” Despite the subjective content of the responses, surveys are used extensively in economic research and also for economic policy purposes.

Today there are many estimating methods of measurement of capacity output; nevertheless, full capacity output continues to be a slippery concept and, therefore, remains controversial within economic theory, attracting the attention of economists, who in spite of the recognition of its unquestionable theoretical significance and practical importance nevertheless are still far from reaching any agreement as to the adoption of a single estimating method.

FULL EMPLOYMENT
In a market economy, a resource is employed when engaged, in exchange for monetary payment, in the production or sale of goods and services. Therefore full employment refers most broadly to employing all the available resources—the productive land, labor, and capital—on hand at a certain time and place. More often, however, full employment refers to the full utilization of labor inputs. The term full employment is closely connected to the concept of unemployment, and achieving a broad appreciation of these intertwined notions requires a historical look at both economic theory and public policy.

ECONOMIC THEORY
Macroeconomics, the study of national economic systems, is the realm of economics devoted to studying full employment and unemployment. Prior to the 1936 publication of John Maynard Keynes’s The General Theory of Employment, Interest, and Money (written as a response to the mass unemployment of the Great Depression), macroeconomics did not exist apart from the broader discipline of economic theory.

When Keynes published The General Theory, most economists believed that market economies were self-adjusting systems that usually operated at full employment and would, on their own, return to full employment after a period of adjustment to external disturbances. Keynes disagreed. “The evidence indicates that full, or even approximately full, employment is of rare and short-lived occurrence” (Keynes 1964, pp. 249–250). Thus The General Theory was offered to contrast Keynes’s ideas about unemployment with the view of the period’s conventional economists, which he called classical economic theory.

According to classical economics, there is no reason for the involuntary unemployment of workers. In this type of economics, wages adjust to equate workers’ supply of labor and employers’ demand for labor. The result is a state of “full employment,” though this does not mean that all workers will be continuously employed. In fact classical economic theory allows for three forms of “voluntary” unemployment in a full-employment economy. (This discussion of full employment and unemployment in economic theory draws on Galbraith and Darity [1994]. Readers interested in a more detailed discussion of the theoretical perspectives discussed in the present essay should consult that volume; most macroeconomics texts offer similar analyses.)

In classical theory, unemployment can exist when a worker moves between jobs, refuses to accept work at the market wage rate, or is prevented from taking a job because of a social decision that keeps wages above their equilibrium level. The first situation describes what is called frictional unemployment and is considered “voluntary” because classical theory assumes that a job is available for that worker at the equilibrium wage rate. (To be more precise, the key wage of interest to classical econo-
mists is the “real” wage, which is the actual or “nominal” wage adjusted for paycheck purchasing power by taking into account the general level of prices.) The second situation is viewed as voluntary because the unemployed person could find work by lowering his or her “reservation” wage and accepting employment at a lower than desired level of pay. The third situation, which exists when a collective-bargaining agreement or minimum-wage law sets a wage above the market rate, is considered voluntary because society as a whole could remove the institutions that interfere with market forces.

In *The General Theory*, Keynes shifts attention from the labor market to the economy as a whole. Since Keynes argued that the total level of employment is a by-product of supply and demand for economic output as a whole, he focused on what determines the economy’s equilibrium level of overall output. The key, he concluded, is total or “aggregate” spending by households, firms, and government (excluding considerations of international trade).

According to Keynes, the economy’s equilibrium output is achieved when aggregate spending (called aggregate demand) absorbs the income earned (called national income). Since this can occur at any number of levels of income, aggregate demand is the crucial determinant of national output and employment. While classical economists focused on labor-market dynamics and assumed that the labor-market always yields employment equilibrium consistent with equilibrium in the overall economy, Keynes argued there is no reason to assume these equilibriums will be compatible. Thus Keynesian economics maintains that the economy could remain indefinitely at a total level of employment that is far below the full-employment level that labor-market considerations alone would generate. In Keynesian theory, there is involuntary unemployment whenever overall economic equilibrium generates a level of employment that falls below the labor market’s market-clearing, “full-employment” level.

Here it is worth noting a difference regarding how full employment is described in “Keynesian economics” and in a portion of Keynes’s *The General Theory*. In Keynesian economics, although there is no necessary connection between the equilibrium employment level generated by aggregate economic activity and the labor market’s “full-employment” level, the labor market can at least be considered a conceptual benchmark, “telling us whether or not we are at full employment” (Galbraith and Darity 1994, p. 147). In a portion of *The General Theory*, however, there is no resort to full employment as this sort of conceptual notion (Keynes 1964, p. 26). Rather, full employment is a much more empirical construct: It exists when an increase in aggregate demand fails to result in more employment. James K. Galbraith and William Darity explain the latter view as follows: “If an expansion of aggregate demand … leads to a higher level of employment, then involuntary unemployment prevailed prior to the expansion. If not, then the economy already was at full employment” (Galbraith and Darity 1994, p. 33).

Keynesian economics (and Keynes’s *The General Theory*) suggests that closing the gap between actual and “full” employment involves boosting aggregate demand via fiscal or monetary policy. The problem, however, is that such macroeconomic policy alone often yields inflation, as economists recognized in the 1960s. At first Keynesians explained the “trade-off” between unemployment and inflation with reference to the Phillips curve, which plots inflation against unemployment for various moments in time and showed an inverse relationship between inflation and unemployment. This curve fit less neatly as an account of the 1970s, however, bolstering an emerging anti-Keynesian movement that eventually produced what is now called New Classical macroeconomics.

Edmund Phelps and Milton Friedman, whose work in the late 1960s suggested that there is no long-run trade-off between unemployment and inflation, offered an early challenge to Keynesian theory. The Phelps-Friedman analysis treats the long-run Phillips curve (again, inflation plotted against unemployment) as a vertical line rising upward from the “natural rate of unemployment.” Moreover the “long run” here does not require a vast period of time. Rather, government efforts to boost aggregate demand will increase inflation without reducing unemployment whenever workers correctly (observe or) expect an increase in prices and insist on an offsetting wage increase.

The doctrine of the natural rate of unemployment is a strong argument against activist macroeconomic management in pursuit of greater employment. In fact the Phelps-Friedman theory indicates that the result of such activism would be higher and accelerating inflation. According to their theory, the main way to reduce unemployment is to raise the rate of labor productivity growth, but since productivity growth stalled during the 1970s, economists’ estimates of the natural rate rose during that decade—from about 5.4 percent in the late 1960s to just over 7 percent in the late 1970s (Bennett 1997, p. 275).

The natural rate of unemployment (which in the early twenty-first century is often called the “non-accelerating inflation rate of unemployment”) is widely believed to have fallen since the 1970s, but the precise rate is not really that important in New Classical macroeconomics. That is because New Classical theory restores the pre-Keynesian belief in an equilibrium alignment of the labor market and the overall economy. As a result of a notion called “rational expectations,” New Classical economics assumes that most observed variations in the unemployment rate are simply changes in the natural rate; since the only exceptions are temporary and random employment
fluctuations in response to surprise events (such as a hike in the price of oil), the economy is, in effect, always at full employment. New Classical theory restores the laissez-faire viewpoint that dominated pre-Keynesian economics.

Among the contemporary economic theorists who have attempted to revive portions of Keynes's macroeconomic policy insights are New Keynesians and Post-Keynesians. New Keynesians accept much of New Classical theory but introduce a number of reasons why wages—nominal wages in some cases and real wages in others—might nonetheless fail to adjust to ensure full employment. The result is a role for government to raise employment by removing wage rigidities or, at least temporarily, by increasing aggregate demand. While most New Keynesians explain unemployment in terms of sticky wages, some offer an explanation rooted in price inflexibility. See, for example, the discussion of New Keynesian economics in Galbraith and Darby's Macroeconomics (1994, pp. 315–319).

Post-Keynesians go further than New Keynesians and reject the notion that wage levels are a significant determinant of employment. Indeed, unlike most New Keynesians, they argue that efforts to make wages more flexible can actually worsen unemployment. Like Keynes, meanwhile, Post-Keynesians emphasize the role of aggregate demand, which they see as liable to sudden fluctuations as a result of volatility in the expectations governing investment. Post-Keynesian theory indicates that the state has an inescapable role to play in stabilizing the economy and maximizing employment by judiciously managing the level and composition of public spending (Pressman 2001, pp. 104–111).

**PUBLIC POLICY**

In response to the Great Depression, a number of economists in the United States and the United Kingdom offered policy-oriented volumes that presented strategies to achieve full employment. Among the most well known is William H. Beveridge's *Full Employment in a Free Society* (1945). Other early books on full employment include Mordecai Ezekiel, *Jobs for All through Industrial Expansion* (1939), and John H. G. Pierson, *Full Employment* (1941). Beveridge defined full employment as follows: "It means having always more vacant jobs than unemployed [workers]. It means that the jobs are at fair wages, of such a kind, and so located that the unemployed can reasonably be expected to take them; it means, by consequence, that the normal lag between losing one job and finding another will be very short" (Beveridge 1945, p. 18).

Beveridge gave the public sector responsibility for influencing and supplementing private activity so as to achieve and sustain full employment. He outlined a three-pronged policy attack on joblessness: There must be enough jobs; industry must be encouraged to locate facilities with an eye to matching job opportunities to labor force skills; and workers must be provided with job vacancy information, relocation assistance, and perhaps even training or job-placement assistance. An annual public budget with outlays in five categories was identified as the main government tool: (1) funds for roads, schools, and other public goods; (2) investments in rail transit systems and other government-owned industries; (3) loans and other incentives to promote private investment (coordinated by a national investment board); (4) subsidies that reduce prices for essential consumer goods; and (5) income-redistribution programs, such as social security, to ensure robust consumer spending.

In 1946 the U.S. Congress passed the Employment Act, proposed by legislators with a view similar to that of Beveridge. According to the legislation, "It is the continuing policy and responsibility of the Federal Government ... to promote maximum employment, production and purchasing power." The Employment Act included provisions establishing the Council of Economic Advisers to the President and requiring an annual Economic Report of the President, designed to track trends in economic performance, review existing economic policies, and recommend policy changes that would better enable the government to achieve its objectives (Bailey 1950, pp. 227–232).

In policy circles, a distinction has long been drawn between three forms of unemployment: frictional, cyclical, and structural. As mentioned above, frictional unemployment exists when workers are between jobs. Cyclical unemployment exists when aggregate demand is insufficient to hire all who are actively searching for work. And structural unemployment exists when there is a skill or geographic mismatch between available workers and unfilled jobs. In the early 1960s the Council of Economic Advisers set an average annual unemployment rate of 4 percent as an "interim target," reflecting their belief that this level was consistent with tackling cyclical unemployment. These and other economic analysts also believed that unemployment could fall further by means of worker training and additional efforts to attack structural and frictional sources of joblessness (Galenston 1966; Gordon and Gordon 1966).

By the mid-1970s, however, the U.S. unemployment rate exceeded 7 percent, leading a frustrated Congress to revise the Employment Act through passage of the Full Employment and Balanced Growth Act in 1978. The new law provided stronger language by substituting "full employment" for "maximum employment" as the nation's employment objective and mandated a 4 percent unemployment rate as the country's primary economic goal. However, in the absence of a requirement that the public sector must serve as "employer of last resort" when citizens are unable to find work, the 1978 change proved to have
little practical impact on economic policy and performance.

Behind the U.S. employment legislation of 1946 and 1978 was a policy debate that continues in the early twenty-first century—a debate over whether citizens should have a publicly guaranteed right to a job. Whether there should be a “right to work” has long received academic and public attention, but President Franklin D. Roosevelt brought the issue to the fore in his 1944 State of the Union Address. In that speech, Roosevelt stated that the nation must be guided by a “second Bill of Rights,” including “the right to a useful and remunerative job” (Roosevelt 1944). (For a much earlier argument in favor of the right to employment, see John R. Commons [1899].)

A number of policymakers who worked on the 1946 and 1978 Employment Acts wanted to secure the right to employment by enabling the unemployed to turn to the federal government for some form of “public works” or “public service” employment. Since the Great Depression, such job opportunities have often been made available to the unemployed, usually on a rather limited basis, through various federal programs (such as the Works Progress Administration, created in 1935, and the Comprehensive Employment and Training Act of 1973). The current focus of U.S. employment policy, however, is on helping workers find training for private employment, and even that effort receives limited public funding. Public service employment and institutional mechanisms needed to establish government as the employer of last resort continue to receive attention from academics (Wray and Forstater 2004; Kaboub 2007), but these ideas have little backing from federal lawmakers.

FULLER, BUCKMINSTER

1895–1983

Richard Buckminster “Bucky” Fuller defined himself as a “random element,” and he has been described variously as an American visionary, architect, mathematician, inventor, designer, philosopher, and a “poet of technology” (Cruikshank 1981). He was the son of Richard Buckminster Fuller (who died when he was 12 years old) and Caroline Wolcott Andrews. He grew up in Maine and attended Milton Academy in Massachusetts. Later he was expelled twice from Harvard University. In his youth, he worked as a mechanic in a textile mill and as a laborer in a meatpacking plant. In 1917 he married Anne Hewlitt. After serving in the navy during World War I, Fuller and his father-in-law, the architect James Monroe Hewlitt, developed a company that produced lightweight, weatherproof, fireproof structures, but the company was unsuccessful and by 1927 Fuller was 32, bankrupt, and jobless. Living in substandard housing in Chicago, Fuller’s young
daughter, Alexandra, died of a contagious disease. Fuller blamed himself, became suicidal, and contemplated jumping into Lake Michigan, but he was saved by an epiphany that he should devote himself fully to the betterment of all humanity. He spent a year without speaking as a discipline to focus his thoughts.

Fuller published *Shelter* magazine in the 1930s. He was science and technology consultant for *Fortune* magazine from 1938 until 1940, then lectured at numerous universities, including Harvard and the Massachusetts Institute of Technology, and in the late 1950s he became a professor at Southern Illinois University, where he and Anne lived in a geodesic dome. In 1972 he was named "World Fellow in Residence" to a consortium of universities in Philadelphia, including the University of Pennsylvania. He retained his connection with both Southern Illinois University and the University of Pennsylvania until his death.

Fuller is perhaps best known for his invention of the geodesic dome. The dome’s design is based on “tensegrity” structures—tetrahedrons (triangular pyramids) and octahedrons (polyhedron with eight faces, resembling two pyramids attached at their bases). The geodesic dome is a perfect symbol to represent Fuller’s life-long examination of nature’s geometry. While Fuller was at Black Mountain College in 1948, using lightweight plastics he designed a small dome that became the first building that could sustain its own weight with no practical limits. Using his focus on nature, he had conceptualized that the natural analytic geometry of the universe is based on arrays of tetrahedra; independent research indicates that the strongest possible homogeneous truss is cyclically tetrahedral.

Fuller coined the word *Dymaxion* (from DYNamic MAXimum tensION) and used it when conceptualizing many of his works, including the Dymaxion map, which was the first map to depict the entire planet earth on a single flat surface without visible distortion of the relative shapes and sizes of the continents. Another feature of the map is that it can be reconfigured to put different regions at the center; this perspective supported his philosophy that people must consider the world’s problems systemically rather than politically or regionally. His conceptualization of “spaceship earth” promoted the idea that the earth provides all that humans need in order to survive, but also that humans need to be wise stewards of these resources. He argued that we are all world citizens and that borders are arbitrary and typically unhelpful constructs. This philosophy led to the creation of his “world game,” a simulation and series of workshops that Fuller designed using the Dymaxion map to teach players how best to use the earth’s abundance.

Fuller devoted his life’s work as to the optimal ways for humanity to survive successfully on earth. He coined the term *ephemeralization*, which refers to the tendency for contemporary technology to be replaced by much smaller, lighter, and more efficient technologies that offer multifunctionality. This was true to Fuller’s basic philosophy of learning from nature and doing more with less and producing less waste. Fuller also introduced the concept of *synergetics*, which refers to holistic engineering structures in nature and the blending of complementary factors that result in a product greater than the sum of its parts.

Some of his other key concepts and inventions include:

- Dymaxion house (1928)
- Aerodynamic Dymaxion car (1933)
- Prefabricated compact bathroom cell (1937)
- Tensegrity structures (1949)
- Geodesic dome for Ford Motor Company (1953)
- Patent on octet truss (1961)

Fuller was nominated for several Nobel Prizes, and he received the Medal of Freedom (the highest national award given to a civilian) for his “contributions as a geometer, educator, and architect-designer” and the Gold Medal award from the American Institute of Architects. He was awarded twenty-five U.S. patents and he received forty-seven honorary degrees. In 1991 *Science* magazine voted the Buckminsterfullerene the “molecule of the year.” The Buckminsterfullerene molecule, which consists of 60 carbon atoms and very closely resembles a spherical version of Fuller’s geodesic dome, was named in his honor.

Functional Form

Chris E. Stout

FUNCTIONAL FORM

A mathematical model involves an explicit set of equations that describe the relationships among the variables contained in the model. It is important to know not only which variables to include in the model, but also the proper functional forms of the mathematical equations. In the natural sciences, the functional forms are often known from the laws of nature. If \( a \) = acceleration, \( t \) = time, and \( d \) = displacement, the laws of physics dictate the functional form \( d = at^2/2 \). The problem of selecting the proper functional form is particularly difficult in the social sciences because the laws of human behavior are not as precise as the laws of nature. Moreover, the social sciences are not like the laboratory sciences, which allow for repeated experiments with the aim of determining the precise mathematical relationships among the variables.

Consider the general functional form for the case of two independent variables \( x_1 \) and \( x_2 \): \( y = f(x_1, x_2, \varepsilon) \), where \( y \) is the dependent variable, \( x_1 \) and \( x_2 \) are the independent variables, and \( \varepsilon \) is the error term representing the variation in \( y \) not explained by \( x_1 \) and \( x_2 \). Although a particular theory might specify the signs of the partial relationships between \( y, x_1 \), and \( x_2 \), the form of the function \( f() \) is typically unknown. The standard procedure is to posit a linear relationship and to estimate the coefficients \( a_0, a_1, \) and \( a_2 \) in the regression equation \( y = a_0 + a_1x_1 + a_2x_2 + \varepsilon \).

The linear form can be viewed as a first-order approximation of the function \( f() \). For many circumstances, such approximations can be quite useful. However, if the continued application of either independent variable has, say, diminishing effects on \( y \), the linear approximation will be invalid when the change in \( x_1 \) or \( x_2 \) is large. Similarly, the linear approximation might be poor if the effect of \( x_1 \) on \( y \) depends on the level of the variable \( x_2 \).

A popular alternative to the standard linear model is to express some or all of the variables in logarithmic form. Consider (1):

\[
\ln(y) = a_0 + a_1\ln(x_1) + a_2\ln(x_2) + \varepsilon_1
\]

This is equivalent to \( y = c(x_1)^{a_1}(x_2)^{a_2}\varepsilon \), where \( a_0 = \ln(c) \) and \( \varepsilon_c = \ln(\varepsilon) \).

Notice that equation (1) is linear as a result of the logarithms, so the coefficients can be easily estimated using linear regression methods. Also, the coefficients have the straightforward interpretation that \( a_i \) \((i = 1, 2)\) is the percentage change in \( y \) resulting from a 1 percent change in \( x_i \).

Other popular specifications include those using powers of the variables and their products. In the two-variable case, a second-order approximation is (2):

\[
y = a_0 + a_1x_1 + a_2x_2 + a_{11}x_1^2 + a_{22}x_2^2 + a_{12}x_1x_2 + \varepsilon
\]

It is important to use the correct functional form to obtain unbiased and consistent coefficient estimates of the effects of the independent variables on the dependent variable \( y \). One way to select the functional form is to use a general-to-specific methodology: Estimate a very general nonlinear form and, through hypothesis testing, determine whether it is possible to pare down the model to a more specific form. In equation (2), if \( a_{11}, a_{22}, \) and \( a_{12} \) are not significantly different from zero, it can be claimed that the linear form is more appropriate than the second-order approximation. When searching over many different functional forms, the usual t-tests and F-tests of statistical significance, as well as the usual measures of fit, such as \( R^2 \), are generally not appropriate, however. As one adds regressors and allows for more general functional forms, the fit of the regression to the data will necessarily improve. Moreover, since every sample has a few unusual observations, there is the danger that a general-specification search will lead to overfitting the data, in the sense of selecting an overly complicated functional form. Hence,
in a specification search of the most appropriate functional form, most researchers use the specific-to-general methodology: Estimate a simple model, and perform a number of diagnostic checks to determine whether the model is adequate. Then estimate a more complicated specification only if there is some sort of diagnostic failure. Some diagnostic tests, such as Ramsey’s (1969) RESET, attempt to determine whether the regression’s error terms are truly random. Others, such as Brown, Durbin, and Evan’s (1975) CUSUM test, attempt to determine whether the regression coefficients are constant over the entire sample. Nonrandom errors and/or nonconstant coefficients indicate that the functional form of the estimating equation is incorrect.

Another method that can be used to select the most appropriate functional form is out-of-sample forecasting (in which the researcher holds back a portion of the observations from the estimation process and estimates the alternative models over the shortened span of data). Forecasts from the alternative models are compared to the actual values of the data held back. The model with the smallest forecast errors is deemed the best.

**FUNCTIONALISM**

The term *functionalism* has been used in at least three different senses in the social sciences. In the philosophy of mind, functionalism is a view about the nature of mental states. In sociology and anthropology, functionalism is an approach to understanding social processes in terms of their contribution to the operation of a social system. In psychology, functionalism was an approach to mental phenomena that emphasized mental processes as opposed to static mental structures.

**FUNCTIONALISM IN THE PHILOSOPHY OF MIND**

Functionalism in the philosophy of mind was first systematically developed in the 1960s as a view about the nature of mental states such as sensations, beliefs, desires, and emotions. It arose in response to questions about the relation between mind and body, in the context of a debate between opposed views known as dualism and materialism. Dualism was defended by the seventeenth-century philosopher René Descartes (1596–1650), who held that minds were nonphysical substances that were not located in space and indeed had no physical properties at all. A major difficulty for dualists has been to explain how mental states, if they have no physical properties, can cause or be caused by physical states of a person’s body. Materialists, by contrast, have held that there are no nonphysical substances, and that mental states are nothing more than physical states.

The best-known materialist views in the 1950s were behaviorism and the identity theory. Behaviorism as a theory of the nature of mental states is sometimes called *logical behaviorism* to distinguish it from behaviorism as a methodological view in psychology. According to behaviorism, mental states were simply tendencies to behave in certain ways under certain circumstances. Behaviorists thus rejected not only dualism, but also the commonsense view that mental states are internal states that are causes of behavior. Identity theorists, on the other hand, held that mental states were identical with states of the central nervous system. The identity theory appeared to rule out by definition the possibility that mental states could be present in any being that did not have a human central nervous system.

Functionalism was intended to be a theory that was compatible with materialism, while avoiding the difficulties of behaviorism and the identity theory. It was motivated in part by the thought that the relation between mind and body is analogous to the relation between software and hardware in a computer. Computational states are defined, not in terms of specific hardware configurations, but in terms of their relations to inputs, outputs, and other computational states. Computational states are *multiply realizable*, that is, they can be realized or implemented by a wide range of different kinds of hardware. Functionalists held that a similar approach could be taken to mental states; that is, mental states could be defined as relations between perceptual inputs, behavioral outputs, and other functional states. For example, the beginnings of a functionalist analysis of pain might point out that it is a state that is produced by potentially harmful sensory inputs, leads to avoidance behaviors, and tends to produce such other mental states as a dislike for whatever caused the pain. According to the functionalist, it is relationships such as these, not a specific physical implementation, that are essential to pain.

Functionalism seems to avoid the difficulties of the other main approaches to the nature of mental states.
Because mental states, like computational states, must be implemented in a physical medium, functionalism seems to make it less mysterious than dualism how mental states can stand in causal relations with physical states of the body. Unlike behaviorism, functionalism is compatible with the view that mental states are internal causes of behavior. And unlike the identity theory, functionalism leaves open the possibility that beings very unlike humans could nevertheless have mental states.

Different versions of functionalism have been developed by different writers. The view described above most closely resembles the machine functionalism defended by Hilary Putnam in a number of papers reprinted in his *Mind, Language, and Reality* (1975). Somewhat different versions were defended by other writers; David Braddon-Mitchell and Frank Jackson offer a useful survey in their *Philosophy of Mind and Cognition* (1996), and a number of the original papers are reprinted in *Readings in the Philosophy of Psychology* (1980), edited by Ned Block.

The most serious difficulty for functionalism is the problem of accounting for conscious experiences, which philosophers call *qualia*. One thought experiment that illustrates the problem involves the apparent possibility of *inverted qualia*. It seems possible in principle that two people could be functionally identical even though their experiences were inverted, so that when one person saw something green, that person had an experience that felt to him or her the way an experience of something red felt to the other. If this is a real possibility, it follows that functionalism cannot be a complete account of the nature of all mental states, since if two people with identical functional properties could nevertheless have different qualia, then qualia cannot be functional states.

**FUNCTIONALISM IN SOCIOLOGY AND ANTHROPOLOGY**

In sociology, functionalism was a theoretical perspective that emphasized that the parts of a social system are interrelated in such a way that none of them can be fully understood except in terms of their effects on the others. The relationships between the parts of a social system constitute the structures of that system, and social structures, social processes, and other social phenomena are to be explained in terms of their functions, which are, for most theorists, their contributions to the continued stable existence of the system. The social systems to which functional analysis was applied ranged from units as small as the family to those as large as international organizations; the phenomena to which functions were imputed included social roles, social norms, devices for social control, and many others.

Functionalism originated in the late nineteenth century in the work of such thinkers as Herbert Spencer (1820–1903) and Émile Durkheim (1858–1917); it was developed in the early twentieth century as an approach to anthropology by A. R. Radcliffe-Brown (1881–1955) and Bronislaw Malinowski (1884–1942); and in the middle decades of the twentieth century, as elaborated by Talcott Parsons (1902–1979) and Robert Merton (1910–2003), it became the dominant perspective in American sociology.

Some functionalist writers were influenced by an analogy between societies and biological organisms, and their concept of social function was explicitly modeled on that of biological function. Radcliffe-Brown, for instance, in “Structure and Function in Primitive Society” (1935, reprinted in Coser and Rosenberg 1976), distinguishes between three sets of sociological problems: *social morphology*, which identifies social structures just as biological morphology identifies organic structures; *social physiology*, which identifies the functions of these structures; and *development*, which studies how new social structures arise, much as evolutionary theory explains the development of new kinds of organisms.

Functionalists have typically thought of the function of a social activity as its contribution to the needs of the society, especially to a social equilibrium, which tends to right itself if disturbed. Durkheim, in the first systematic development of a functionalist approach, distinguished between the cause of an activity such as the punishment of crime, on the one hand, and its function, on the other. The practice of punishment may initially be caused by an intention to deter crime or achieve justice, but its function, according to Durkheim, is to maintain our intense emotional disapproval of crime. Although a particular practice or activity may not initially be caused by a recognition of the function it will serve, Durkheim holds that its serving a useful function is nevertheless part of the explanation of the continued survival of that practice.

Malinowski, who introduced the term *functionalism* into anthropology, identified seven fundamental biological needs: metabolism, reproduction, bodily comforts, safety, movement, growth, and health, as well as derived needs, such as the need to produce goods and the need to regulate behavior. He held that the function of social processes was ultimately to satisfy these individual needs. Radcliffe-Brown rejected this view, going so far as to write that “as a consistent opponent of Malinowski’s functionalism I may be called an anti-functionalist” (“Functionalism: A Protest” [1949], reprinted in Kuper 1977, p. 49). Although he regarded the concept of function as central to anthropology, in his view the function of social processes was not to satisfy individual needs, but rather to support or preserve social structures. Radcliffe-Brown’s view is often called
Structural functionalism to distinguish it from Malinowski’s.

The sociologists most closely associated with functionalism in the mid-twentieth century were Talcott Parsons and Robert Merton. (The terms functionalism and structural functionalism are both used to describe their work.) Parsons identified four functions that any social system needs in order to achieve and maintain equilibrium. These were: adaptation, or the acquisition and distribution of resources from the environment; goal attainment, which involves determining which goals of the system have priority and determining how to achieve them; integration, which involves coordinating relationships between various social actors to enable them to function smoothly together; and latent pattern maintenance-tension management, which involves transmitting values that will keep actors motivated to act in ways that are necessary for the continued functioning of the system.

Merton’s contributions included his distinction between manifest functions, which are consequences that agents in the system recognize and intend to produce, and latent functions, which are not intended or recognized. Whereas Parsons had tended to emphasize manifest functions, Merton stressed that many important functions are latent. Merton also introduced the concept of dysfunctions, which are consequences of an activity that have negative effects on the stability of the system.

By the late 1970s, functionalism was no longer the dominant paradigm in sociology, in part because of the perceived conservatism of its emphasis on equilibrium, and its consequent lack of attention to social conflict and change, and in part because it was seen more as a set of abstract categories than as a testable empirical theory. In the 1980s and 1990s, there was some interest in a neo-functionalism sociology that attempted to preserve the insights of functionalism, especially as represented in Parsons’s work, while addressing its perceived failings.

FUNCTIONALISM IN PSYCHOLOGY

In psychology, the term functionalism refers to an American school of psychology that was influential at the turn of the nineteenth century. Functionalism developed in response to the earlier structuralist view advanced by Wilhelm Wundt (1832–1920) and Edward B. Titchener (1867–1927). Structuralist psychology used an introspectionist methodology to attempt to identify basic elements of conscious experience into which more complex experiences, or structures, could be analyzed. Functionalism, by contrast, emphasized psychological processes rather than static psychological structures. Functionalism also stressed the role of the mind as a mediator between the environment and the needs of the organism; like the pragmatist philosophy that influenced it, functionalism held that psychological processes should be understood in terms of their effects. The most influential contributors to this school were the pragmatist philosophers William James (1842–1910) and John Dewey (1859–1952), and the University of Chicago psychologist James Rowland Angell (1869–1949). Although functionalism influenced later approaches to psychology, as a distinct school it faded from view in the early decades of the twentieth century, as behaviorism rose to prominence.

FUNCTIONINGS

The concept of functionings was introduced by the Indian economist Amartya Sen in Commodities and Capabilities (1985), in the context of the “equality of what” debate. This debate involved scholars interested in the definition of social justice after the influential work of the American political philosopher John Rawls (1971). Rawls defined social justice in terms of equality of rights and of priority
given to individuals who receive the smallest quantity of basic resources (which he called primary goods). This view represented a striking break with the utilitarian tradition focusing on individuals’ subjective well-being and launched a debate about the quantity that should be equalized across individuals in a just society: welfare, resources, opportunities, and so on.

Sen criticized Rawls’s choice of a resource metric for the definition of social justice on the grounds that different individuals may have different abilities to transform resources into achievements of various kinds. He called such achievements functionings, encompassing all achievements, not only actions (doings) but also states of the body and the mind (beings), that might be considered relevant. For instance, an individual’s level of happiness is a functioning, as well as his marital status, his income, the kind of job he has, and how much he works. Sen, however, did not propose to define social justice as equality of some index of functionings across individuals, or as priority for those who have the smallest level of functionings. He argued that what is important, out of concern for freedom and responsibility, is not that people actually have good levels of functionings, but that they have access to such levels. The set of functioning levels that an individual is able to achieve is called a capability, or capability set, in his theory, and he favors a definition of social justice in terms of equality of capabilities (or priority for the worst off in terms of capabilities).

One difficulty with the concepts of functionings and capabilities as used in Sen’s theory is that they are so large that one must find ways to determine how to weigh the importance of various functionings in the construction of a synthetic index. Whether individuals’ personal preferences or expert opinion about prudential values should be relied upon in such an exercise is open to controversy. A list of important functionings has been proposed by Martha Nussbaum. There are also alternative theories of justice that combine the double concern for unequal abilities on the one hand and freedom and responsibility on the other hand in different ways, as in Richard Arneson’s equality of opportunity for welfare (which singles out subjective welfare as the only ultimately relevant functioning) or Ronald Dworkin’s equality of resources (which includes personal abilities in the definition of resources). Some authors (Elizabeth Anderson, John Baker, and Marc Fleurbaey) have argued that achievements (functionings) and not only opportunities (capabilities) are relevant for the evaluation of individual situations in terms of social justice.

The notion of functionings has been influential in empirical measurements of standards of living, most notably in the United Nations Development Program construction of a “human development index” that adds education and health data to income statistics for the comparison of countries. Many other applications are being pursued. A Human Development and Capabilities Association was created in 2004.

FUNDAMENTALISM
Fundamentalism originally referred to an American Protestant movement occurring at the turn of the twentieth century. It emerged from an interdenominational revivalist movement led by the evangelist preacher Dwight Moody (1837–1899). In the early part of the twentieth century, fundamentalism came to stand for opposition to certain trends in modern society, including the rise of liberal theology, science’s challenge to religious beliefs, and increasing secularization of society in general.

In the early twenty-first century, scholars have referred to a worldwide fundamentalist movement that includes various faith traditions. This more recent use of the term fundamentalism shows its usefulness for capturing the form and functions of a great many religious groups and their agendas. As used by scholars, the term is meant to describe, not evaluate.

At the heart of fundamentalist movements, then, is their revolt against modernism and their call to return to the basic beliefs and practices of their original community

Marc Fleurbaey
and, most importantly, to the basic beliefs found in sacred texts such as the Bible and the Qur’an. Scholars’ composite pictures of fundamentalist groups often represent them as energetic, sometimes aggressive, and, contrary to current stereotypes, only occasionally violent.

Fundamentalists feel that certain developments associated with modernism undermine religious identity and their own religious worldview. They believe these developments undermine the ability to lead a morally pure life and, in some cases, a life that prepares for the afterlife. Their concern is not with developments in technology and science per se but only with those developments that challenge their religious worldview and/or have moral implications—as when Darwinian evolutionary theory spawned social Darwinism with its counter-Christian ethic of survival of the fittest. As this example of social Darwinism indicates, fundamentalists’ complaints about modernism are not altogether different from the complaints of many non-fundamentalists.

In North America, the term fundamentalism has often been used interchangeably with the term evangelical, although more so at the beginning of the fundamentalist movement than in the twenty-first century. Evangelical refers to the winning or saving of souls. To evangelize, then, means to lead others to becoming saved. North American fundamentalists are all about being saved and saving others: saved by believing in Jesus as the Lord and saved by accepting the Bible as the inerrant word of God.

For fundamentalists, being saved involves more than attending church or trying hard to lead a good life. Being saved, say the fundamentalists and evangelicals, entails no less than a total commitment to Christ and a total belief in the Bible. To be a North American Protestant fundamentalist is, then, to embrace a biblical perspective that is clear, free from contradiction, and rejecting of alternative, non-fundamentalist worldviews. Being ecumenical is not, then, a part of the fundamentalist agenda. Therefore, North American Protestant fundamentalism, like other forms of fundamentalism around the world, runs counter to the dominant worldview in most societies today, a worldview that values pluralism and accepts there being multiple perspectives on what is true and valuable.

Nor is it a fundamentalist agenda to promote a separation of religion and state, a separation that has been central in North American and European democratic traditions. This is even more evident in Arab regions of the world where Islamic fundamentalism works to unite societies under Islamic law and under Islamic religious leadership.

Worldwide fundamentalism has been, then, both separatist and integrationist in spirit and political life. That is, while fundamentalists speak of the need to separate one’s self from the unsaved and from this sinful or corrupt world they also speak of the need for humankind to become a single, religious community.

Fundamentalism is not simply about returning to a distant past or living in the present according to truths and prescriptions revealed in the distant past. It is also about working and waiting for an imagined future. In North American Christian fundamentalism, the imagined future is the Second Coming of Christ or Parousia, a time when sinners (non-believers) will be judged and the Kingdom of God will be established.

This theme of there being a cataclysmic future event or time when sinners will be judged and the righteous and true believers will prevail is not just a theme in North American Protestant Christian fundamentalism. It is also a theme in non-Christian, non-Western fundamentalist movements. All fundamentalist movements uphold the general theme that today’s secular, pluralistic society will be replaced by a mono-religious society.

Non-fundamentalists often negatively stereotype fundamentalists. For example, fundamentalists are often pictured as being less educated on average, more authoritarian and dogmatic, anti-science, militant, and narrow-mindedly literal in their reading of sacred texts such as the Bible. However, the results of responsible research have shown each of these stereotypes to be distortions of the truth. In fact, fundamentalists make up a diverse group with respect to education, personality traits, and views about science and militancy. Furthermore, fundamentalists generally acknowledge the need to reflect and interpret when reading the sacred text. For fundamentalists, in general, discerning the revealed truth in the sacred text does not require taking each word, phrase, sentence, or portion literally.

Fundamentalism has and will continue to appeal to large segments of societies, especially in troubled times and in times of rapid transition. Its greatest appeal is in its offering clarity where there is doubt, order and continuity where there is disorder and discontinuity, and hope for being good and being saved where there is despair over being sinful and being lost. Fundamentalism appeals to a significant and diverse group for its providing a worldview and way of interpreting life that provides meaning, guidance, and personal satisfaction.

Despite these positive attributes, fundamentalism will likely continue to be rejected by the majority and for several reasons. First, its appeal to return to previous ways runs counter to the majority’s desire to develop new ways that reflect new conditions in modern life. Second, its appeal to adopt an uncompromising perspective, one that does not value alternative faith traditions and alternative worldviews, runs counter to the majority’s desire to value cultural and religious diversity so as to live harmoniously in a pluralistic society. Third, its appeal to believe in the
Fundamentalism, Christian

inerrant, revealed truth of sacred texts runs counter to the philosophical and scientific ways of thinking that pervade modern academic and political institutions.

FUNDAMENTALISM, CHRISTIAN

Christian Fundamentalism is a twentieth-century development that originated in American Protestant circles. While most attention to the phenomenon still focuses on the United States, thanks to missionary endeavors, it is now represented around the Christian world.

While many casual observers often speak of fundamentalism as if it were the equivalent of Protestant conservatism, traditionalism, or orthodoxy, scholars point to significant differences. The word *fundamentalism* appears in no encyclopedias or dictionaries before the 1920s, a fact which signals that some new reality was on the scene, one that would evoke new terminology. Fundamentalism in its broadest sense is a defensive reaction against uncongenial and threatening forces that are often code-named *modernism*. The conservatisms that were already on the scene ordinarily were disengaged from politics, concentrating as the fundamentalists saw it, apart from the work of God or the story of the world’s creation in the Bible. Another strand of thought that went into fundamentalist formation was a view that the world would end in a cataclysm, after which through one of a variety of scenarios, Jesus would return to rule for a millennium.

Fundamentalists also favored the adjective *literal* as opposed to *symbolic* or *allegorical* when treating biblical miracles or teachings that Jesus was born of a virgin and was physically resurrected. The lynchpin of fundamentalism, however, came to be fiercely defended theories of biblical inerrancy, which held on a kind of philosophical ground that there were and could not have been any errors of historical, geographical, scientific, or any other sorts in the Bible.

Early fundamentalists faced scorn in the culture at large and were opposed by moderates in the Protestant denominations, yet they endured. In 1942 some of them organized as a national association, a move that was countered a year later by more moderate fundamentalists who came to call themselves *evangelical*. Evangelicalism, popularized by figures like Billy Graham, agreed with fundamentalism on most teachings, but evangelicals were culturally more moderate and they came to outnumber the hard-core fundamentalists.

As decades passed, moderate evangelicals came to prosper more than did fundamentalists. Fundamentalists tended to be separatist, reluctant to cooperate with even conservative Protestants who did not share every detail of their doctrines. Evangelicals moved more toward the cultural mainstream, and their leaders often shared platforms and programs with certain kinds of Catholics and mainline Protestants. Evangelicals and fundamentalists, who share so much by way of doctrine, have adopted quite different styles, and the separatism of fundamentalism has held it back in the competition for souls and influence.

For decades, fundamentalists professed to be and ordinarily were disengaged from politics, concentrating as they did on evangelizing, converting, and preparing believers for life in heaven. In the final third of the twentieth century, however, while some stayed back from the frays, most fundamentalists plunged eagerly into politics. The Supreme Court decisions that disallowed prayer in public schools in 1962 and 1963, followed by a decision that allowed for legalized abortion in 1973, galvanized fundamentalists. They did an about-face and developed sophisticated approaches to mass media, originally through radio but later using television and the Internet, and made political alliances with Republicans. In coalition of Bible colleges, missionary societies, charitable agencies, and radio stations and programs that carried the message and work forward.

The main challenges in the 1920s were *evolution*, the teaching that human descent resulted from natural selection and, as the fundamentalists saw it, apart from the work of God or the story of the world’s creation in the Bible. Another strand of thought that went into fundamentalist formation was a view that the world would end in a cataclysm, after which through one of a variety of scenarios, Jesus would return to rule for a millennium. with conservatives they came to have considerable power in electoral politics and in legislation.

Social scientists observe fundamentalists in various social circumstances and classes. Often typed as rural and lower-class in the early years, many of them became prosperous urbanites and suburbanites, and were known for erecting large churches and producing television programs, supporting colleges such as Jerry Falwell’s Liberty University in Virginia, and favoring participation in the affluent society with a zest that would have appalled their grandparents. Christian rock music, Christian films and best-selling books, and Christian self-help programs took on the trappings of their worldly counterparts. In doing so, fundamentalists helped create a culture within the culture, a kind of Jesus-centered replica of their more secular counterparts.

Most fundamentalists inherited and fostered efforts to convert others, as their ancestors in less-threatened nineteenth-century evangelical Protestantism had done. Large numbers of them, particularly in the dominant Southern Baptist tradition, insisted on adult baptism after conversion, and brought a biblical concept of being “born again” into the cultural spotlight. There have been few pacifists among the fundamentalists, most of them being strong supporters of military ventures by the United States and expressing themselves as dedicated patriots. On such grounds, they were suspicious of cultural, social, and political moderates and liberals, and often lumped them together as the “other” who was “secular humanist.” Fundamentalists tend to create psychic boundaries and spiritual distance from others, fearing that ecumenical or interreligious ventures would lead to a weakening of the faith that as militants they claim is the only valid form of approach to God.

FUNDAMENTALISM, ISLAMIC
The term Islamic fundamentalists commonly refers to groups who seek to promote the role of Islam in political, social, and economic life, and who contend the necessity of establishing an Islamic state based on Islamic sharia law. The term Islamic extremists, in contrast, refers to fundamentalist groups who operate outside the law and espouse violence to attain political power.

Islamic fundamentalist movements in the Middle East and North Africa claim to represent a periphery whose political recognition and economic interests have been excluded by incompetent, corrupt, and authoritarian pro-Western regimes. The sluggish performance of these states vis-à-vis the demands of civil society for greater political participation and socioeconomic equality has led many disenfranchised young people to support Islamic fundamentalist movements as a mode of protest. The limited ability of modern nation-states to overcome these domestic problems has become increasingly acute as a result of fiscal restrictions on their redistributive capacities in the era of globalization. In addition, Islamic fundamentalist movements view the globalization process as an imperialist plot to pollute their countries with Western businesses and consumption patterns, and to impose painful adjustment reforms arranged by international financial institutions. Moreover, these fundamentalist movements are often motivated by political grievances with what they consider to be inconsistent U.S. foreign policy toward the Islamic world.

Islamic fundamentalist movements often use populist rhetoric laced with anti-Western attitudes, and they rely on previously mobilized Islamic mission-oriented groups who have not benefited from open-door economic policies. Islamic fundamentalists perceive their relationship with the incompetent pro-Western regimes as a zero-sum game. In the majority of cases, these movements occupy part of the political space as important countermovements or sources of opposition to existing authoritarian (and mostly secularist) regimes, and as such they have enjoyed relative legitimacy. The tyrannical states, in turn, have responded with security crackdowns and tougher regimentation measures, and in so doing have pushed moderates toward more radical positions. The polarization between Islamic fundamentalist movements and their countries’ incumbent regimes has been growing since the mid-1980s as the globalization process has deepened.

Historically, Muslim responses to the challenge of Western colonialism have affected the current tension between Islamic movements and the regimes under which they operate. The colonial era resulted in the incorporation of the countries of the Middle East and North Africa into the capitalist world system, and in the consolidation of internally bureaucratic and externally territorial states. The colonial legacy also contributed to the deficient nature of state building and capitalist development in the region. The most problematic legacy from the colonial era
is overdeveloped states coupled with underdeveloped social structures. The state apparatus during the colonial period was not created by national bourgeoisie but by foreign colonial administrators who inflated the size of the bureaucratic machine, especially its military and security sectors, to serve the colonialists’ own purposes and to confront any possible resistance. The rulers of the postcolonial states produced much the same type of effect via the creation of authoritarian systems with a lopsided size of state to society features but without a hegemonic and independent social class. Furthermore, under the forms of capitalism artificially established, the state role has been even more exaggerated in order to promote delayed capitalist development in the name of national interest. In such circumstances, social classes are excessively dependent on the state, and the absolute primacy of the state resulted in an embryonic class structure in these countries immediately after their independence.

Most governments in the Middle East and North Africa are characterized by a coercive security apparatus, a lack of legitimacy, and inefficient administration. They also tend to be nondemocratic, despite their differing or even contradictory ideological bases. When these states’ attempts at capitalist development were undertaken by a small group of crony capitalists operating within a rigid bureaucracy, the military and security sectors resorted to raw coercion, and they repressed Islamic fundamentalist movements in order to preserve their invested interests.

Although the state is supreme, the society is primordial and indeterminate in terms of its economic and political functions. The primacy of the state has in fact hindered the development of Islamic fundamentalist movements in the Middle East and North Africa, and most Islamist movements in the region have not developed organizational strength. They have, however, exhibited greater militancy toward the state and less coordination with civil society, which has resulted in greater repression by the state. Although exclusion and repression by the authoritarian states helped forge a sense of solidarity in Islamic society, the fundamentalist movements have exhibited a lack of centralized bargaining power at the national level. Islamist fundamentalist groups tend to push their own agendas regardless of the deleterious consequences for civil society as a whole, which has ultimately caused them to become more marginalized.

FUNERALS

Polish anthropologist Bronislaw Malinowski once observed that when persons are actually “faced by death,” they turn almost immediately instead “to the promise of life.” In other words, “death and its denial—immortality”—coincide (1954, p. 47). In many ways funerals express these dualities and their contrasting, ambivalent feelings and realities. In effect, funerals commonly aim to turn death, which appears to represent an end, into its opposite, a transition to another kind of life. Moreover, they seek to reintegrate the group and especially those most bereaved following the sense of loss that death has eventuated.

The funeral is almost always a social occasion, a ceremony at which those with a relationship to the deceased or the bereaved are assembled in order to mark the change in status that death has occasioned. The function of the funeral is to dispose of the corpse and to recognize the sense of loss among the bereaved. It also seeks to demonstrate to all of the assembled that while a particular person has died, life itself and the group go on. Hence while the disposal of the cadaver, an essential feature of the funeral, expresses dread of the corpse and a desire to be rid of it and its impurities while also confirming the reality and finality of the death, almost everything else about the funeral asserts immortality and continuity: of the soul, the community, a relationship with the deceased, and faith in the future.

The public nature of the funeral as well as the common understanding that attendance at it trumps most other social obligations both reflect the fact that death is never just the concern of the immediately bereaved or only the affliction of those who have died. While ostensi-
bly carried out for the dead person, the funeral rites in fact have important effects and benefits for the living, both as individuals and a group. These rites commonly entail practices that aim to confront death with repeated assertions of life and expressions and ceremonial displays that make the bereaved feel that they are not completely abandoned. Moreover, they aim to show that death may momentarily bring about chaos, but the funeral reinstates order. It does so with ritual.

At a funeral's successful conclusion, the dead body is disposed of and becomes separated from the person who inhabited it and the living are endowed with an enhanced sense of solidarity as they mourn and console one another back to life, while incorporating the deceased as part of a living memory. While this process is largely metaphorical in most funeral ceremonies, in some cases, the process is quite literal. Among the Melanesians of New Guinea, for example, parts of the dead person are ingested by some of the bereaved and later vomited. This practice allows the spirit of the deceased to remain within, and a sense of solidarity both among the mourners and between the mourners and the deceased to be established while the physical remains of the corpse are removed. The Catholic rite of communion, in which the body and spirit of Christ is ingested by those who recall him through the eating of consecrated bread and wine, may be understood as a reiteration of such funereal rites. All this shows that death ends a life but not a relationship.

Funerals may generally be divided into component parts. First comes the preparation of the corpse for disposal and its display. This may include washing, anointing or embalming, dressing, and even some forms of restoring the body. Often this is accompanied by a temporary public placement of the cadaver among the living, although always camouflaging its decay. This might, for example, include placing flowers or perfumes around the body. This use of flowers is as old as Neanderthal man, whose skeletons in the caves of Iraq were found covered with a layer of pollen, suggesting they were enclosed with flora.

In some cultures this public display may last several days—sometimes called “lying in state.” In others, this is called “the viewing,” and often the body is “improved” or adorned so that the repulsion of death does not overwhelm the living. Public placement includes placement of the body on a catafalque, sometimes in a casket, in shrouds, on a pyre, or some other visible site. In its origins, this public display of the corpse may have served as a means of making certain that the person was truly dead, as the certification of death was historically by no means always as accurate as it is today. The presence of the prepared corpse in public view thus provided both an opportunity to persuade everyone that the person was indeed deceased while also in some way mitigating the dreadful vision of death and its reminder of universal mortality.

When bodies were placed in private homes, particularly in Victorian England, they were often put in the parlor, the room in which people gathered. This led to the parlor taking the name, “living room,” as a way of offsetting the stigma and dread associated with the placement of corpses in it. In time, in North America, the placement of the corpse was moved from people’s homes and parlors or living rooms to special sites that came to be called “funeral parlors” or “funeral homes.” At times, funerals are carried on in places of worship, though in a number of religious traditions the corpse is considered defiling and hence not put in what are considered sacred places.

While a growing corps of professionals handle the preparation of the body, in some religious traditions volunteers from within the community of deceased or the bereaved carry this out. Thus, for example, among traditionally observant Jews, the preparations are carried out by the Chevra Kadishah (holy fellowship) whose ritual washing, grooming, clothing, and preparation of the dead for burial are called tahara (purification).

The second part of the funeral consists of the rites and ceremonies of farewell. These include prayers, eulogies, and the marking of the mourners in some visible way. In some cultures, wailing or other forms of mourning are part of the funeral. But the possibilities of rites are as rich and varied as human culture. Thus, for example, among the Hmong of Vietnam, practices used during funeral ceremonies include: sacrificing a live chicken to place at the head of a deceased person in order that the soul of the chicken can lead the soul of the deceased person back to their ancestral home; burning gold paper money for the deceased to take on the journey home; and calling a shaman to communicate with the souls of the deceased to understand their wishes and communicate those wishes to family members. In general, the ceremonies of the funeral act to control the emotional damage that death may otherwise inflict by holding it within the framework of ritual behavior.

Part of the farewells consists of presenting the idea that death is really an alternative form of life, and the funeral initiates the transition from one form of life to another. In this sense, funerals may be seen as liminal or threshold rites, as described by Arnold van Gennep in his Rites of Passage (1960). For some groups, Jews for example, this period of transition should be short so as to hasten reintegration. For others, the farewell is extended so as to hold onto to the deceased a bit longer.

To assure the passage from death to a new life, the corpse must in some way be transformed. As Robert Hertz explained, “to make an object or living being pass from this world into the next, to free or create the soul, it must...
be destroyed,” and then only as the “visible object vanishes,” and becomes invisible, can it be “reconstructed in the beyond, transformed to a greater or less degree” (1960, p. 46). The removal or destruction of the dead body and the beginning of mourning marks the third and final part of the funeral. Among Hindus this is accomplished with the burning of the body and in India with floating it along the holy Ganges River. Among the Abrahamic faiths, this ends with the removal of the body for burial, although increasingly in modern society cremation is chosen as an option by many.

The transformation of the corpse is paralleled by a transformation of the bereaved into mourners. This is often marked either by activities they carry on at and after the funeral that publicly demonstrate their sense of loss. In some cases, the bereaved may tear their garments or hair, as if to reflect the tearing down of their own veneer of civility and social order that death itself has initiated. Of course by making this sort of rending ceremonial, funerary practices emotionally rein in the act and thereby assist the mourners in exercising self-control and limit the trauma of loss in public and to the collective life. The bereaved may be sequestered for a period of mourning that parallels the period of the deceased’s journey to a new life. The conclusion of mourning marks the true end of the funeral, when the dead have reached their spiritual destination and the bereaved re-enter a full social life. Often this is marked with eating and drinking, activities associated with continuity and life.

**FUTURE SHOCK**

American author Alvin Toffler first used the term *future shock* in 1965 to refer to the psychological disorientation and physical stress experienced by individuals and societies when radical changes occur within short periods of time. In *Future Shock*, the 1970 book that popularized the term, Toffler argued that human beings have limited abilities to adapt to social and technological transformations. Thus, he argued, it was the rate of alteration in personal and social life, and not just the direction of change, that posed unique psychological challenges to contemporary human beings.

Toffler believed that future shock would become a common psychological and physical state in advanced industrialized nations due to the speed with which technologies were transforming all aspects of society. In 1970 he already saw what he perceived as symptoms of future shock. These included an increasing impermanence in everything from interpersonal relationships to the life of institutions, a rise in individual and collective mobility, an increase in social diversity, and an acceleration in the consumption of goods and novel experiences. Toffler believed that these changes might soon outstrip human abilities to cope with them. For that reason, he argued that societies must actively manage the technological and social changes under way.

Soon after the publication of *Future Shock*, the title concept became a staple of popular writing on technological change. In the scholarly literature, researchers deployed the term within the field of organizational theory to address the possible consequences of technological change in the workplace and the possibility that they could be effectively managed. Education scholars also invoked the concept as they studied how to prepare students for the rapid changes taking place in society. Though it remained popular in the organizational and educational literature, the concept of future shock never developed analytical purchase across the social sciences. As the Internet came on the scene in the mid-1990s, however, the term saw a brief resurgence. By the late 1990s, it was often used by political scientists studying Internet-based political processes and trying to forecast the effects of technological change in that arena.

Within the social sciences, many of the phenomena Toffler pointed to in 1970 have been subsumed under other analytical paradigms. Writing at about the same time as Toffler, sociologists Alain Touraine (1971) and Daniel Bell (1973) pointed to the rise of *postindustrial society*. In the mid-1990s, sociologist Manuel Castells argued that the *network society* has emerged. In the movement from postindustrial to network society, scholars have integrated many of Toffler’s concerns with the consequences of technological change, but they have let go of the core features of

FUTUROLOGY

Futurology is the rigorous attempt to anticipate future developments, relying heavily upon social-science methods. Few futurologists actually try to forecast future conditions, but instead prefer to identify alternative possibilities and to critique naive forecasts that others may have proposed. Critical futurology has deep historical roots. For example, in 1872 Edward Jarvis addressed popular concerns that the United States was experiencing too much immigration through careful demographic analysis that showed the country was in little danger of becoming primarily foreign born.

In the 1960s a futurology craze gripped American intellectuals, many of whom wished to serve as advisors to the Kennedy-Johnson administration’s New Frontier or Great Society and the competition with the Soviet Union cold war. The RAND corporation sponsored studies that combined the views of many experts into unified forecasts concerning a wide range of possible technological and social developments. Among the sequels were two visionary books, The Year 2000 (1967), by Herman Kahn and Anthony J. Wiener, and Towards the Year 2000 edited by Daniel Bell (1967).

In the 2000s conferences such as the annual meetings of the World Future Society offer diverse prospectives. Serious journals, such as Futures and Futures Research Quarterly, carry projections, scenarios, theory-based extrapolations, and expert judgments about the future.

A projection analyzes recent trends mathematically, then runs the trends forward in time to estimate particular variables, such as population, economic activity, or the diffusion of a new technology. In 1971 Jay Forrester used the simple computers of his day to model the interplay of economic and social variables on a global scale through systems dynamics projections. The approach was famously used in the 1972 Club of Rome report, Limits to Growth, predicting that the global economy would soon crash because of resource depletion, but in retrospect the numerous assumptions seem arbitrary, and the crash has not yet occurred. The report remains influential as a cautionary tale but not a prediction.

The point of a scenario is not to predict, but to clarify, presenting a coherent, internally consistent picture of a future possibility so that planners and scholars can think more clearly and creatively. The scenarios in the Kahn–Wiener and Bell books imagined the fall of the Soviet Union and the birth of the World Wide Web. In 2003 British astronomer Royal Sir Martin Rees examined realistic scenarios for many of the ways humankind could become extinct during this century.

A theory sketches the future implied by a particular set of formal ideas. Pitirim Sorokin argued that every great civilization follows a cycle from ideational culture based on a transcendent ideology such as a religion, to sensate culture that is secular, empirical, and destined for collapse, followed by a new ideational phase. While agreeing with Sorokin’s general approach, Rodney Stark and William Bainbridge argued that civilization will not secularize in the long run, because religion responds with constant revival and innovation.

Scientific and technical expertise can identify the possible implications of discoveries. In 2000 the U.S. National Science Foundation considered the implications of nanotechnology for industry, medicine, environmental sustainability, space exploration, national security, and scientific understanding of nature. The finding that the societal impact would operate indirectly, led to an examination of the possible future convergence of nanotechnology with biotechnology, information technology, and new cognitive technologies.

Given that futurologists seldom attempt to predict precise outcomes, one may wonder how futurology differs from science fiction (SF), a genre of literature that often concerns speculations about the future and is sometimes praised for insight about the implications of science and technology. Sociological research suggests that SF has pri-
marily four ideological dimensions: (1) “hard-science” stories favorable to technological innovation; (2) “new-wave” stories critical of technological development, emphasizing aesthetics and social science rather than natural science; (3) fantasy stories in which magic or the supernatural are more important than technology or science; and (4) the time dimension anchored in classical SF such as the century-old works of Jules Verne, H. G. Wells, and Edgar Rice Burroughs. Arguably, the first two of these dimensions might qualify as futurology, if the authors built upon a solid basis of knowledge in the natural or social sciences, using narrative fiction as a way of rendering their scenarios more vivid.

*William Sims Bainbridge*
G7 COUNTRIES

In the 1970s, declining economies and a worldwide recession sparked a series of informal meetings among leaders of the world's major economies. In April 1973 the finance ministers of France, the United Kingdom, West Germany, and the United States met in Washington, D.C., to discuss ways to stabilize their economies and the failing international economic order. Two years later, in 1975, as the Western nations faced an oil crisis, trade deficits, unstable national currencies, the proliferation of weapons of mass destruction, threats of war, and chronic unemployment, the president of France requested a gathering of leaders from the industrialized nations. The meeting, intended to discuss ways to circumvent the bureaucratic conflict and economic nationalism hindering international economic cooperation, took place in Rambouillet, France, in November 1975. Present were the heads of government of France, Italy, Japan, the United Kingdom, the United States, and West Germany. The group became known as the Group of Six (G6). The following year, Britain, Canada, France, Germany, Italy, Japan, and the United States met as the Group of Seven, commonly referred to as the G7. The subsequent annual meetings of the G7 provided a forum in which leaders of the seven nations could discuss and coordinate actions on economic and commercial matters.

FROM THE G7 TO THE G8

The G7 became the G8 in 1998, when Russia was admitted formally to the group (it had been participating in summit meetings since 1994). Since 1998, G8 summits have extended their agendas beyond discussions of macroeconomic issues to include wider discussions of global economic concern, including microeconomic issues and regional security, transnational issues such as the environment, drug trafficking, and human rights. The G8 was criticized by emerging nations for forming an elite and undemocratic alliance in which policies were formulated by wealthy nations and then imposed upon the rest of the world. Developing nations protested that their interests were not addressed during the G8 meetings. These criticisms resulted in the formation of the Group of 20 (G20) in 1999. The G20 consists of finance ministers and central bank governors from nineteen industrialized and emerging market countries plus the European Union. The International Monetary Fund and the World Bank also participate in G20 meetings on an ex-officio basis. The G20 nations include the G8 plus Argentina, Australia, Brazil, China, India, Indonesia, Mexico, Russia, Saudi Arabia, South Africa, South Korea, and Turkey. The establishment of the G20 was intended to open up an informal dialogue on international financial affairs among a broader group of countries than the G8 alone.

Despite its noninclusive nature, defenders of the G8 contend it has promoted the global economic good. From this perspective, the G8 is responsible for stabilizing the international monetary system after the collapse of the limited gold standard. Some observers, including the former U.S. president Ronald Reagan, believe the G8 underwrote capitalism's victory in the cold war. The topic upon which the G8 has had the greatest influence is trade. During summit meetings leaders are able to collaborate on political and economic decisions. The influence of the G8 on multilateral trade negotiations resulted in the formation of the General Agreement on Tariffs and Trade 1994...
(GATT 1994) and the creation of the World Trade Organization (WTO) in 1995. The G8’s primary role is to expand the realm of capitalism, and one of the most enduring legacies of the G8 is the expansion and maintenance of mutual trust among the member nations. The G8’s stated goal has shifted over time from a forum dealing essentially with macroeconomic issues to an annual meeting with a broad-based agenda that addresses a wide range of international economic, political, and social issues.

BIBLIOGRAPHY

G8 COUNTRIES

The Group of Eight (G8) is an annual meeting of the leaders of the world’s major industrial states. The purpose of the G8 is to have world leaders meet informally on economic and political issues facing their individual countries and the international community as a whole. Initially proposed by President Valéry Giscard d’Estaing of France and Chancellor Helmut Schmidt of Germany, the first summit, held at Rambouillet, France, in November 1975, included only six countries: France, the United States, Britain, Germany, Japan, and Italy. The impetus of the meeting was to discuss the oil crisis. In 1976 President Gerald R. Ford called for a second summit, which initiated the annual nature of the meetings and established it as an institution. When Canada joined the group in 1976 it became known as the G7.

From 1976 to 1990 the G7 met annually; sometimes on the eve of the summit it included fifteen developing countries as in the 1989 Paris summit. Russia became part of the post-summit discussions from 1991 to 1994. These meetings are sometimes referred to as the P8 or Political Eight. Russia had partial membership as it was excluded from financial and other economic discussions. Russia obtained full membership in 1998 and in doing so, the G8 was born. There is an additional member of both the G7 and G8: the European Union. The chair and location of the G8 are selected in a rotating manner starting with France, the United States, the United Kingdom, Russia (as of 2006), Germany, Japan, Italy, and Canada. The position of chair is held for one full calendar year. The host country proposes the summit location and agenda and organizes preparatory meetings.

Despite the lack of formal structure, the G8 has had an effect on the world. A significant change to international organizations resulted from the 1995 Halifax, Canada, summit, where leaders agreed to amend the rules and procedures of the World Bank and the International Monetary Fund (IMF). The agenda for the summits change from year to year and focus on the most pressing economic and social issues. During the Okinawa, Japan, meeting in 2000 the G8 agreed to provide further funding to fight infectious disease. The meeting also focused on issues regarding information and communications technology. The 2001 Geneva, Switzerland, meeting created the Global Fund to fight infectious diseases such as AIDS, tuberculosis, and malaria.

Because of the cooperation and dialogue of the world’s leaders accomplished through the G8, it has also attracted the attention of protestors. Probably the largest and most violent meeting was held in Genoa, Italy, in 2001, where an anti-capitalist protestors was shot and killed while hundreds of others were injured during a clash with police. In subsequent years the G8 has tried to open discussions with nongovernmental organizations and include other developing nations.

The G8 meeting hosted by Britain in Perthshire, Scotland, was interrupted by terrorist attacks on London’s transit system on July 7, 2005. Tony Blair, the host of the meeting, left for a brief time to visit London while the other leaders remained to continue the discussion and agenda that was set. The issue of global terrorism has been on the agenda most years since 1978.

GABRIEL (PROSSER)

1776–1800

The enslaved revolutionary known only as Gabriel was born near Richmond, Virginia, at Brookfield, the Henrico County plantation of Thomas Prosser. By Virginia standards, Brookfield was a large plantation, with a population
of approximately fifty enslaved laborers. Unfortunately, the identity of Gabriel's parents is lost to history, but he had two older brothers, Martin and Solomon. Most likely, Gabriel's father was a blacksmith, the occupation chosen for Gabriel and Solomon; in Virginia, the offspring of skilled bondpersons frequently inherited their parent's profession.

Status as a craft artisan provided the young blacksmith with considerable standing in the slave community, as did his ability to read and write. In the 1780s, it was not yet illegal to teach Virginia slaves to be literate, and effective artisans needed the rudiments of literacy. According to tradition, his teacher was plantation mistress Ann Prosser. As Gabriel grew to be an unusually tall young man, even older slaves looked to him for leadership, a habit uncommon in African culture. By the mid-1790s, as he approached the age of twenty, Gabriel stood "six feet two or three inches high," and the muscles in his arms and chest betrayed nearly a decade in Brookfield's forge. A long and "bony face, well made," was marred by the loss of two front teeth and "two or three scars on his head" (Egerton 1993, p. 22). In later years, a racist legend arose which held that Gabriel wore his hair long in naïve imitation of Samson, in hopes that his locks would give him extraordinary strength. But contemporary descriptions say only that his hair was cut short and was as dark as his complexion. According to journalist James T. Callender, blacks and whites alike regarded him as "a fellow of courage and intellect above his rank in life" (p. 22).

During his years as an apprentice blacksmith, Gabriel married a young slave named Nanny. Little is known about her, including the identity of her owner. She does not appear in the few extant Brookfield records; most likely she lived on a nearby farm or tobacco plantation. But well into the twentieth century, area blacks believed that Nanny bore him children, who much later went under the surname of Randolph.

In the fall of 1798 Gabriel's old master died, and ownership of Brookfield passed to twenty-two-year-old Thomas Henry Prosser. An ambitious young man with a townhouse in Richmond and a lucrative auction business, Prosser maximized his profits by hiring out his surplus slaves. Even the most efficient planters could not find tasks enough to keep their enslaved artisans occupied year around, and many masters routinely hired out their craftsmen to neighboring farms and urban businesses. Despite all of the work to be done at Brookfield, Gabriel spent a considerable part of each month smithing in Richmond for artisans long on orders and short on labor. Although still a slave under Virginia law, Gabriel enjoyed a rough form of freedom. Indeed, his ties to the plantation became so tenuous that several historians have identified him as a free man.

Emboldened by this quasi liberty, in September 1799 Gabriel moved toward overt rebellion. Caught in the act of stealing a pig, a delicacy slaves used to supply their families with protein, Gabriel refused to endure the verbal abuse of its owner, a white neighbor. Instead, he wrestled his tormentor to the ground and bit off the better "part of his left ear" (Egerton, p. 31). Under Virginia law, slaves were not tried as whites. They were prosecuted under a colonial statute of 1692 that created special segregated tribunals known as courts of oyer and terminer, composed of five justices of the peace. On October 7 Gabriel was formally charged with attacking a white man, a capital crime. Although found guilty, Gabriel escaped the gallows through an antiquated clause that since the Revolution had been denied to white defendants. Slaves yet possessed the right to "benefit of clergy" (p. 31), which allowed them to avoid hanging in exchange for being branded on the thumb with a small cross if they were able to recite a verse from the Bible.

Gabriel's branding and incarceration served as a brutal reminder that despite his literacy and special status, he remained a slave. By the early spring of 1800, his fury began to turn into a carefully considered plan to bring about his freedom, as well as the end of slavery in Virginia. As a literate man who moved among urban artisans, Gabriel surely knew that several states to the north had recently passed laws for gradual emancipation, and that New York had finally approved such a statute in 1799. As he explained it to his brothers Solomon and Martin, slaves and free blacks from Henrico County would gather at Brookfield on the evening of August 30 to march on Richmond. If Governor James Monroe and the town leaders agreed to Gabriel's demands for black liberty and an equitable distribution of the property, the slave general intended to "hoist a white flag" and drink a toast "with the merchants of the city" (Egerton, p. 51).

The uprising collapsed just before sunset on the appointed day, when a severe thunderstorm hit the Richmond area. The chaos of the storm convinced two Henrico slaves, Tom and Pharoah, that the revolt could not succeed. They informed their owner of the conspiracy, and he hurried word to Governor Monroe. As the state militia closed in, Gabriel escaped south by way of the swampy Chickahominy River. After hiding along the James River for nearly two weeks, Gabriel risked boarding the schooner Mary. Captain Richardson Taylor, a former overseer who had recently converted to Methodism, willingly spirited Gabriel downriver to Norfolk. There Gabriel was betrayed by a slave crewman, who had heard of Monroe's $300 reward for Gabriel's capture. Returned to Richmond under heavy guard, Gabriel was quickly tried and found guilty of "conspiracy and insurrection" (Egerton, p. 109). On October 10, 1800, the young revolutionary died with quiet composure at the town gallows.
near Fifteenth and Broad Streets. He was twenty-four. In 2002 the Richmond city council formally adopted a resolution proclaiming Gabriel to be "an American patriot and freedom fighter" (Richmond Times-Dispatch, October 11, 2002).

**GALBRAITH, JOHN KENNETH**

**1908–2006**

John Kenneth Galbraith was an institutional economist, Harvard professor, advisor to presidents, bureaucrat, ambassador to India, raconteur, caustic wit, and man of letters. His concepts of countervailing power, the affluent society, conventional wisdom, want creation, and the technostructure of the industrial state have become part of the modern vernacular and the battle for the controlling metaphors of economics and politics. Born on a farm in southern Ontario, Canada, he attended Ontario Agricultural College, graduating in 1931. His family and community background are detailed in his memoir, *The Scotch* (1964). A desire to understand the causes of the Great Depression led him to seek a PhD in agricultural economics at the University of California, Berkeley, graduating in 1934. The influence of Progressive Era economists such as Richard Ely (1854–1943), John R. Commons (1862–1945), and Thorstein Veblen (1857–1929) was in evidence and it created an atmosphere accepting of the New Deal initiatives of President Franklin D. Roosevelt (1882–1945).

Galbraith’s first job involved research in agricultural economics under the tutelage of Harvard professor John D. Black (1883–1960), who was well connected in Washington, D.C. Before beginning, Galbraith served as a summer intern in the Agricultural Adjustment Administration. There he learned the role of power in the economy as he witnessed southern congressmen stopping the payment of agricultural subsidies to tenant farmers (mostly blacks). During World War II (1939–1945), Galbraith was placed in charge of price control and rationing in the Office of Price Administration. The political pressure from business was intense, charges of communism flew, and Galbraith was fired in 1943.

Galbraith’s writing and analysis led to a stint at *Fortune* magazine from 1943 to 1948. During this time, he also participated in the Strategic Bombing Survey to assess the role of air power in winning the war. The survey concluded that strategic bombing played a minor role and that ground troops were essential in both Germany and Japan. Galbraith later objected to what he called “military Keynesianism”—stimulating the economy via military spending at the expense of social programs.

Upon his controversial return to Harvard, Galbraith wrote *American Capitalism* (1952), in which he argued that a decentralized private economy excelled in production and innovation. He further maintained that concentration and bigness were inevitable. Countervailing the power of buyers, unions, and government would be more effective in controlling the seller’s power than traditional antitrust.

In his best-selling *Affluent Society* (1958), Galbraith observed that wealthy economies were no longer typified by scarcity. In fact, corporations maintained themselves by creating demand, rather than merely responding to it, as the "conventional wisdom" had it, producing what he called the "dependence effect." He observed a “social imbalance” between abundant private consumption goods and inadequate publicly provided goods, such as education, clean air and water, and transportation. His description of "the family which takes its mauve and cerise, air-conditioned, power steered, and power-braked car out for a tour passes through cities that are badly paved, made hideous by litter, blighted buildings, billboards and posts" (1958, pp. 199–200) has become legendary and still applies today.

*The New Industrial State* (1967) describes giant corporations that are run and planned by a hired bureaucratic technostructure rather than owners and that strive for survival and independence rather than profit maximization. Advertising, information management, and access to government are key assets. The economy cannot be under-
stood without attention to the use of power in both politics and business. Robert M. Solow contested Galbraith’s argument that giant corporations controlled the economy (1967). But, after subsequent decades of mergers, Galbraith’s concerns seem warranted. Solow also objected to Galbraith’s “revised sequence” of consumption (want creation rather than only prior want fulfillment) by asserting that advertising only serves to cancel other advertising. Galbraith’s concerns drew the label of “sociologist” from Milton Friedman (1912–2006), and along with Galbraith’s argument that public planning must balance the private planning of the corporate technostructure, the label of “socialist.”

Galbraith questioned the monotheistic worship of gross domestic product as the test of a good society and wondered if the same energy (and the discipline of economics itself) might be better directed toward social harmony, aesthetic enjoyment, and leisure. Galbraith remained a social critic until his death in 2006.

GALTON, FRANCIS
1822–1911

Cousin to Charles Darwin and a talented statistician, Sir Francis Galton had an influence on social science that was profound. His major contributions to mathematical statistics included the initial development of quantiles and linear regression techniques. Along with F. Y. Edgeworth and Karl Pearson, he developed general techniques of multiple regression and correlation analysis, statistical devices that serve as substitutes for experiments in social science. Galton had a major impact on economics, and with W. R. Greg, was instrumental in creating the “science” of eugenics.

Galton was born in Birmingham, England, on February 16, 1822, and died on January 17, 1911, in Haslemere. He spent two years (1836–1838) at King Edward’s School in Birmingham, underwent a medical apprenticeship in Birmingham, then studied for a year (1839–1840) at the medical school of King’s College, London, before entering Trinity College, Cambridge in 1840. Galton read mathematics at Trinity, from which he graduated without honors.

After inheriting a substantial fortune on the death of his father in 1844, Galton embarked on an African exploration. He published an account of his travels in 1853, and joined the council of the Royal Geographical Society. Galton was elected Fellow of the Royal Society in 1856, and served as Secretary of the British Association from 1863 to 1867.

Galton’s focus on heredity was first manifested in the 1869 publication, Hereditary Genius, an attempt to marshal evidence in favor of the proposition that mental ability is inherited. In it, Galton, who presumed that mental ability is correlated with reputation in a given profession, examined the scores of two hundred candidates for the Mathematical Tripos at Cambridge as well as those of seventy-two candidates for civil service positions.

In 1883 Galton published Inquiries into Human Faculty and Its Development, in which he discussed the ideas now known as eugenics. Here, his argument began as an attack on the race-neutral accounts of ability in classical economics (Galton 1907, p. 207). Darwin’s endorsement (Darwin 1871, pp. 138–139) gave warrant to Galton’s eugenic ideas. Galton’s claims for the importance of “race”—that is, characteristics preserved by inheritance in distinction to characteristics acquired by custom—was challenged in his time by the assertion that it was implausible that a child of Quaker parents raised in the North American woods by aboriginal people would show the “gentle altruistic nature of his progenitors” (Reid 1897, p. 945). This challenge would lead to twentieth-century studies of identical twins raised in separate environments.
Galton's study of eugenics illustrates his creativity as a researcher. He was, for example, ingenious in his use of composite photography to help identify inherited characteristics. "The individual faces [of criminals]," he wrote, "are villainous enough, but they are villainous in different ways, and when they are combined, the individual peculiarities disappear, and the common humanity of a low type is all that is left" (1907, p. 11). Because there is no reason to believe that criminality is inherited, Galton is partially correct in his deductions—that is, in his claim that there is no specifically criminal type. Of course, since Galton's time the idea that there is such a thing as a "low type" of humanity has been discounted. Similarly, the argument that ability is inherited by race has been questioned, notably by Tukufu Zuberi (2001), who argues that race is a concept devoid of biological meaning and is instead socially constructed.

Despite the fact that many of his conclusions about genetic differences are questioned, if not disproven, today, Galton's work reveals his integrity regarding test results—that is, his willingness to acknowledge cases where the data does not match his presuppositions. An example can be found in his attempt to use his system of fingerprint identification to establish a racial hierarchy, on the basis of the belief that a "higher" race would have less uniform fingerprints. Galton presupposed that the fingerprints of black people would be more uniform than those of white people, but confessed an inability to observe this in the data.

**GAMBLING**

Gambling and games of chance have been popular throughout history. The globalization of gambling has passed through a number of cycles. More so than in the past, gambling is viewed as a socially acceptable form of entertainment. While gambling activities can take many forms and vary across cultures and jurisdictions, most individuals gamble for enjoyment, for entertainment, to socialize, and to try their luck without experiencing many negative repercussions.

**PATHOLOGICAL GAMBLING**

Gambling can be viewed on a continuum, ranging from non-gambling to social gambling to pathological gambling. While most adults gamble without experiencing many adverse consequences, a small proportion of adults (0.4–3%) experience significant gambling-related problems, with an even larger proportion of adolescents (4–6%) reporting major gambling-related problems. The essential characteristic associated with pathological gambling is that it is a persistent and recurrent maladaptive gambling behavior that negatively disrupts personal, familial, social, economic, and vocational pursuits. Given the widespread proliferation and expansion of government-regulated and sponsored forms of gambling, gambling is quickly becoming a prominent social policy issue.

Pathological gambling, conceptualized as an impulse-control disorder, results in an individual's inability to stop his or her gambling in spite of multiple negative consequences. While a greater number of males experience pathological gambling compared to females (estimates are that a ratio of 3:1 exists), pathological gamblers frequently experience a preoccupation with gambling, the need to substantially increase the amount and frequency of their wagers, have great difficulty stopping or reducing their gambling, and become extremely irritable when trying to limit their gambling. These individuals often gamble to escape problems or relieve stress, return to gambling in order to recoup losses, frequently lie to family members, peers, and friends in order to conceal their gambling losses, and commit illegal behaviors (both within and outside the home) to finance their gambling. Pathological gamblers jeopardize familial, peer, and vocational relationships in order to continue gambling and help relieve financial difficulties resulting from their gambling behavior.

There is considerable discussion as to whether some forms of gambling may be more problematic than others. Some research suggests that machine gambling (e.g., slot machines, video poker machines, video lottery terminals) and Internet gambling may be more problematic to some individuals because of their relatively low cost and the frequency and speed of playing while simultaneously allowing the player to go into a disassociative state. Other
research suggests that there are definite differential patterns of playing and preferences for different forms of gambling depending upon one's age, accessibility of venues, gender, and ethnic and cultural background.

An emerging body of literature suggests that certain familial factors (high rates of family gambling problems, substance abuse problems, spouse or partners with a gambling problem), biological factors (including brain chemistry and functioning, physiological indicators of arousal and the need for stimulation, genetic considerations), attentional problems, and a wide variety of physical health problems (including cardiovascular and gastrointestinal problems and chronic pain) are associated with pathological gambling disorders. Personality disorders related to impulsivity, sensation seeking, a high degree of risk-taking, antisocial personality disorders, oppositional defiant disorders, compulsivity, psychoticism, and neuroticism, and cognitive distortions (erroneous beliefs including an illusion that one can control the outcome of random events, a lack of recognition of the notion of independence of events, the belief in a system to “beat the odds”) have similarly been linked to pathological gambling.

From a psychological perspective, pathological gamblers have been reported to exhibit high anxiety, depression and depressive symptomatology, suicidal ideation and suicide attempts, and a wide range of personality and mental health disorders. There is also a growing body of evidence to suggest that pathological gamblers have a variety of comorbid alcohol and substance abuse problems. While there is no personality profile of a pathological gambler per se, there are indications that an individual's psychological and mental state make certain individuals more susceptible to both gambling and the development of a gambling problem.

In spite of the large number of adverse behavioral traits associated with gambling, it is not unusual for individuals to fail to recognize their problems. They tend not to acknowledge their gambling problem and fail to seek help. Their perceived solution often rests on the “big win.”

GAMBLING AMONG CHILDREN AND TEENS
Although problem gambling has been primarily thought of as an adult behavior, considerable research indicates that it remains a very popular activity among both children and adolescents. Whether one is gambling for money on personal games of skill, cards, dice, sporting events, or lottery tickets, a high percentage of children and adolescents worldwide have been found to engage in different forms of gambling.

Studies conducted since the 1990s suggest that gambling activities remain particularly attractive to today's youth and that its popularity is on the rise among both children and adolescents. Prevalence studies conducted in the United States, Canada, New Zealand, Europe, and Australia all confirm the rising prevalence rates of youth involvement in both legal and illegal forms of gambling. While approximately 80 percent of high school students report having gambled for money during the past year, 4 to 6 percent of adolescents exhibit serious gambling problems, with another 10 to 14 percent of adolescents remaining at-risk for developing a serious gambling problem.

Adolescent pathological gamblers, like their adult counterparts and independent of the negative consequences resulting from their excessive gambling, continue to chase their losses, exhibit a preoccupation with gambling, and have an impaired ability to stop gambling in spite of repeated attempts and their desire to do so. The growing body of research with adolescents suggests that gambling and problem gambling is more popular among males than females, adolescent prevalence rates of problem gamblers are higher than those reported by adults, and there is a rapid movement from social gambler to problem gambler. Adolescent problem gamblers report initiating gambling at an early age (approximately ten years of age) as compared with peers who report gambling but have few gambling-related problems. These adolescents are greater risk takers in general and on gambling tasks in particular, exhibit lower self-esteem, exhibit higher depressive symptomatology, remain at heightened risk for suicide ideation and suicide attempts, have poor general coping skills, and report a significant number of major traumatic life events (e.g., parental loss, divorce).

Individuals with gambling problems are also more likely to report school- or work-related problems. Personality traits reveal adolescent pathological gamblers are more excitable, extroverted, and anxious, tend to have difficulty conforming to societal norms, experience difficulties with self-discipline, exhibit more anxiety, exhibit higher levels of impulsivity, and remain at increased risk for the development of multiple addictions.

NEW FORMS OF GAMBLING
New forms of gambling continue to be developed. With more and more governments sanctioning and regulating a multitude of different forms of gambling, its accessibility has never been easier. Problem gambling is not associated with single-trial learning. Very few individuals become addicted to the lure of gambling after their first initiation. Pathological gambling remains a progressive disorder with certain identifiable risk factors developing over time accompanied by periods of euphoria and depression.

The gambling environment today is significantly different from that of past generations. Because of its widespread acceptability, its popularity, and the enormous
revenues generated from gambling, the growth of the gaming industry continues. Gambling is viewed as significantly less harmful than other potentially addictive behaviors including substance abuse, alcohol abuse, and cigarette smoking.

New forms of gambling and games will continue to emerge. Efforts at developing effective empirically sound practices concerning prevention and treatment programs have yet to be realized. Given the widespread accessibility, social acceptance and new technologies bringing gambling into the home, there remains speculation that the prevalence of pathological gambling will likely increase.

Jeffrey L. Derevensky

GAME THEORY

Game theory is a branch of mathematics used to analyze competitive situations whose outcomes depend not only on one’s own choices, and perhaps chance, but also on the choices made by other parties, or players. Because the outcome of a game is dependent on what all players do, each player tries to anticipate the choices of other players in order to determine his own best choice. How these interdependent strategic calculations are made is the subject of the theory. Game theory was created in practically one stroke with the publication of Theory of Games and Economic Behavior in 1944 by mathematician John von Neumann (1903–1957) and economist Oskar Morgenstern (1902–1977). This work was a monumental intellectual achievement and has given rise to hundreds of books and thousands of articles in a variety of disciplines.

The theory has several major divisions, the following being the most important:

Two-person versus n-person. The two-person theory deals with the optimal strategic choices of two players, whereas the n-person theory (n > 2) mostly concerns what coalitions, or subsets of players, will form and be stable, and what constitutes reasonable payments to their members.

Zero-sum versus nonzero-sum. The payoffs to all players sum to zero (or some other constant) at each outcome in zero-sum games but not in nonzero-sum games, wherein the sums are variable; zero-sum games are games of total conflict, in which what one player gains the others lose, whereas nonzero-sum games permit the players to gain or lose together.

Cooperative versus noncooperative. Cooperative games are those in which players can make binding and enforceable agreements, whereas noncooperative games may or may not allow for communication among the players but do assume that any agreement reached must be in equilibrium—that is, it is rational for a player not to violate it if other players do not, because the player would be worse off if he did.

Games can be described by several different forms, the three most important being:

1. Extensive (game tree)—indicates sequences of choices that players (and possibly chance, according to nature or some random device) can make, with payoffs defined at the end of each sequence of choices.

2. Normal/strategic (payoff matrix)—indicates strategies, or complete plans contingent on other players’ choices, for each player, with payoffs defined at the intersection of each set of strategies in a matrix.

3. Characteristic function—indicates values that all possible coalitions (subsets) of players can ensure for their members, whatever the other players do.

These different game forms, or representations, give less and less detailed information about a game—with the sequences in form 1 dropped from form 2, and the strategies to implement particular outcomes in form 2 dropped from form 3—to highlight different aspects of a strategic situation.

Common to all areas of game theory is the assumption that players are rational: They have goals, can rank outcomes (or, more stringently, attach utilities, or values, to them), and choose better over worse outcomes. Complications arise from the fact that there is generally no dominant, or unconditionally best, strategy for a player because of the interdependency of player choices. (Games in which there is only one player are sometimes called games against nature and are the subject of decision theory.)
A game is sometimes defined as the sum-total of its rules. Common parlor games, like chess or poker, have well-specified rules and are generally zero-sum games, making cooperation with the other player(s) unprofitable. Poker differs from chess in being not only an \( n \)-person game (though two players can also play it) but also a game of incomplete information, because the players do not have full knowledge of each other’s hands, which depend in part on chance.

The rules of most real-life games are equivocal; indeed, the “game” may be about the rules to be used (or abrogated). In economics, rules are generally better known and followed than in politics, which is why game theory has become the theoretical foundation of economics, especially microeconomics. But game-theoretic models also play a major role in other subfields of economics, including industrial organization, public economics, and international economics. Even in macroeconomics, in which fiscal and monetary policies are studied, questions about setting interest rates and determining the money supply have a strong strategic component, especially with respect to the timing of such actions. It is little wonder that economics, more than any of the other social sciences, uses game theory at all levels.

Game-theoretic modeling has made major headway in political science, including international relations, in the last generation. While international politics is considered to be quite anarchistic, there is certainly some constancy in the way conflicts develop and may, or may not, be resolved. Arms races, for instance, are almost always nonzero-sum games in which two nations can benefit if they reach some agreement on limiting weapons, but such agreements are often hard to verify or enforce and, consequently, may be unstable.

Since the demise of the superpower conflict around 1990, interest has shifted to whether a new “balance of power”—reminiscent of the political juggling acts of European countries in the nineteenth and early twentieth century—may emerge in different regions or even worldwide. For example, will China, as it becomes more and more a superpower in Asia, align itself with other major Asian countries, like India and Japan, or will it side more with Western powers to compete against its Asian rivals? Game theory offers tools for studying the stability of new alignments, including those that might develop on political-economy issues.

Consider, for example, the World Trade Organization (WTO), whose durability is now being tested by regional trading agreements that have sprung up among countries in the Americas, Europe, and Asia. The rationality of supporting the WTO, or joining a regional trading bloc, is very much a strategic question that can be illuminated by game theory. Game theory also provides insight into how the domestic politics of a country impinges on its foreign policy, and vice versa, which has led to a renewed interest in the interconnections between these two levels of politics.

Other applications of game theory in political science have been made to strategic voting in committees and elections, the formation and disintegration of parliamentary coalitions, and the distribution of power in weighted voting bodies. On the normative side, electoral reforms have been proposed to lessen the power of certain parties (e.g., the religious parties in Israel), based on game-theoretic analysis. Similarly, the voting weights of members of the European Union Council of Ministers, and its decision rules for taking action (e.g., simple majority or qualified majority), have been studied with an eye to making the body both representative of individual members’ interests and capable of taking collective action.

As game-theoretic models have become more prominent in political science, they have, at the same time, created a good deal of controversy. Some critics charge that they abstract too much from strategic situations, reducing actors to hyperrational players or bloodless automatons that do not reflect the emotions or the social circumstances of people caught up in conflicts. Moreover, critics contend, game-theoretic models are difficult to test empirically, in part because they depend on counterfactuals that are never observed. That is, they assume that players take into account contingencies that are hard to reconstruct, much less model precisely.

But proponents of game theory counter that the theory brings rigor to the study of strategic choices that no other theory can match. Furthermore, they argue that actors are, by and large, rational—they choose better over worse means, even if the goals that they seek to advance are not always apparent.

When information is incomplete, so-called Bayesian calculations can be made that take account of this incompleteness. The different possible goals that players may have can also be analyzed and their consequences assessed.

Because such reconstruction is often difficult to do in real-life settings, laboratory experiments—in which conditions can be better controlled—are more and more frequently conducted. In fact, experiments that test theories of bargaining, voting, and other political-economic processes have become commonplace in economics and political science. Although they are less common in the other social sciences, social psychology has long used experiments to investigate the choices of subjects in games like prisoners’ dilemma. This infamous game captures a situation in which two players have dominant strategies of not cooperating, as exemplified by an arms race or a price war. But doing so results in an outcome worse for both than had they cooperated. Because mutual cooperation is
not a Nash equilibrium, however, each player has an incentive to defect from cooperation.

Equally vexing problems confront the players in another well-known game, chicken. Not only is cooperation unstable, but noncooperation leads to a disastrous outcome. It turns out that each player should defect if and only if the other player cooperates, but anticipating when an opponent will do so is no mean feat.

Since the invention of game theory in the mid-1940s, its development has been remarkable. Two Nobel prizes in economics were awarded to a total of five game theorists in 1994 and 2005 (including John Nash of the film A Beautiful Mind fame), but many other recipients of this prize have used game theory extensively. In addition, game-theoretic modeling has progressed rapidly in political science—and, to a lesser extent, in the other social sciences—as well as in a variety of other disciplines, including biology, business, and law.

GANDHI, INDIRA

1917–1984

Indira Priyadarshini Gandhi (born November 19, 1917) was twice elected to hold the position. Daughter of India's first prime minister, Pandit Jawaharlal Nehru (1889–1964), she was introduced to the vagaries of political instability early in life. As someone who participated in the anticolonial national movement in the 1930s and 1940s as a youngster, and saw the carnage that accompanied the partitioning of British India into the independent nations India and Pakistan in 1947, Gandhi experienced firsthand the challenges and uncertainties experienced by a fledgling democracy. In this regard, her formative years introduced her to the political cultures that she would negotiate as one of independent India's most charismatic and controversial figures.

After attending educational institutions in Europe and India, she married an Indian National Congress (INC) activist named Feroze Gandhi (1912–1960) in 1942. Her sons, Rajiv and Sanjay, were born in 1944 and 1946 respectively. Following the deterioration of her marriage, she moved to Delhi to support her father as he prepared to contest India's first national election in 1951. The 1950s and early 1960s were a period of political education and preparation for Gandhi as she rose rapidly in the ranks of the INC, becoming a minister in the government formed by Lal Bahadur Shastri (1904–1966) soon after her father's death on May 24, 1964. In 1965, when war with Pakistan broke out, she emerged as a strong contender for the INC leadership with the backing of a cohort of INC leaders named the Syndicate. Warding off challenges from numerous constituencies within the party, and with the backing of the Syndicate, she became India's fifth prime minister.

From 1971 onward, Gandhi consolidated her dominance. In late 1971, civil war and the secessionist movement of East Pakistan led to the Indian Army's invasion of East Pakistan in the third Indo-Pakistan war since 1947. With the creation of the independent nation-state of Bangladesh in 1971, Gandhi's personality-centered political style became pronounced. Partly to underscore India's growing geopolitical stature in the cold war, she encouraged the development of India's nuclear program, which conducted a successful nuclear test in 1974. Even as India made economic gains in some areas, she undermined India's constitutionally mandated federalism when, unlike her father, she steadily undercut the authority of regional political leaders in order to consolidate power at the center. Her regime witnessed the arrival of a distinctively populist style of government, most apparent from her use of the slogan “Garibi Hatao” (“remove poverty”). While these changes bolstered her authority, they also made her the brunt of popular discontent, which became strident in the 1973–1974 period because of food shortages and inflation. Popular unrest and legal assaults on Gandhi's power precipitated, in June 1975, the declaration of a state of emergency by her government.

The only period of authoritarian rule in post-independence India and a phase denounced as one of the darkest of the postcolonial period, the state of emergency lasted from 1975 to 1977. Controversial constitutional
amendments, censorship, and assaults on civil liberties were accompanied by the arrest of thousands of party workers, and perhaps most notoriously, the forced sterilization campaigns prompted by Gandhi’s son Sanjay Gandhi (1946–1980). These policies raised severe discontent, but Prime Minister Gandhi misjudged the popular mood in 1977 and called parliamentary elections in which her party was comprehensively defeated.

The Janata Party government that came to power in 1977 under the prime ministership of Morarji Desai (1896–1995) did not survive for long, but the period after the state of emergency marked a decisive shift in Indian politics with the restoration of India’s parliamentary democracy and the reversal of many of the authoritarian policies adopted by Gandhi. The INC itself split in the wake of the election debacle, and Gandhi sought to build a new political base for herself, one drawn largely from ethnic and religious minorities. Her reemergence as a political leader coincided with infighting in the Janata Party government, and in 1980 Gandhi was voted back to power as India’s eighth prime minister.

Gandhi’s second term in office was weighed down with problems in the Punjab, where the rise of Sikh militancy accompanied Sikh demands for an independent state. Matters escalated in mid-1984 with Operation Bluestar, when she ordered the Indian Army to storm the Golden Temple in Amritsar, one of the holiest Sikh shrines, to remove militants hiding in its premises. This act of desecration, accompanied by the excessive use of military force, has remained a source of enormous controversy. On October 31, 1984, Gandhi was gunned down by her Sikh bodyguards as she was walking out of her residence. The assassination triggered a pogrom against Sikhs in New Delhi and other northern Indian cities.

Gandhi’s political career has left a deep imprint on Indian politics, not least through her descendants. Her son Rajiv Gandhi (1944–1991) became prime minister in 1984, and his widow Sonia Gandhi emerged during the late 1990s as the leader of the Congress Party. “Vote-bank” politics, with which Indira Gandhi is often identified, has remained an enduring facet of Indian political culture long after her death.

GANDHI, MOHANDAS K. 1869–1948

Mohandas Karamchand Gandhi was born in Porbandar, Gujarat, India, on October 2, 1869, the youngest son in a family of four children. Due to his father’s position as a local politician, the family was subject to transfer within the province, and the Gandhis moved to Rajkot when Gandhi was seven years old. He completed his primary and secondary studies there, and at age thirteen, in keeping with Indian custom at that time, was married (to Kasturba Kapadia).

As a young husband, Gandhi exhibited intense jealousy and sexual voracity. However, his sexual appetite would become the source of great guilt throughout his adult life. This began after his father fell ill and Gandhi became his constant bedside companion. One evening, a trusted uncle arrived to temporarily relieve Gandhi of his responsibility. Gandhi jumped at the chance to be with his wife, and during his absence, his father died. Gandhi never forgave himself, and the vow of celibacy (known as *brachmacharya*) that he took later in life may have involved atonement for this event.

Gandhi left for college in Bhavnagar, about ninety miles from Rajkot, soon after his father’s death, with the intention of replacing his father as provider for the extended family. Though he had always been an exemplary student, his college studies suffered because of his melancholy and his guilt intensified when he ultimately returned home defeated.

Not long after his return from Bhavnagar, a family advisor suggested that he travel to England to study law. Gandhi spent three years in England, and was “called to the Bar,” or made an official barrister, in 1891. He then returned to India to begin a legal practice.

However, Gandhi was afraid to speak out in court. In fact, his first trial ended so badly that he refunded his client’s money. He did have an aptitude for drawing up legal documents and briefs, however, and was offered a job with a Rajkot merchant who did business in South Africa. After much deliberation, Gandhi decided to accept the post in South Africa for one year.

In South Africa, Gandhi immediately encountered racial discrimination. Though also British subjects, Indians were not permitted first-class accommodations,
always had to give way to British whites, and were treated very poorly in general. Gandhi objected to every indignity, but when his employer stepped in to solve the problem for him, Gandhi backed down and tried to ignore the insult; however, shortly before he was to return to India, the government sought to impose an annual £25 tax on indentured servants who had finished their tenure and continued to work in South Africa. The tax applied to each adult family member, and in many instances would have equaled almost as much as the family’s earnings for a full year. It was an obvious ploy to reduce farming competition for white farmers. Gandhi was outraged and met with Indian businessmen to explain the situation. At their behest, Gandhi remained in South Africa to campaign against the tax.

In 1894 Gandhi founded the Natal National Congress, patterned after the National Congress of India, and soon after returned to India to drum up support. The Green Pamphlet, Gandhi’s first political treatise on the plight of South African Indians, was widely distributed in India and roused greater support for the cause. After returning to South Africa in 1904, Gandhi bought and ran the Indian Opinion newspaper to spread the word among Indians living there. At the end of that same year, in order to run the paper more efficiently, Gandhi set up his first commune—the Phoenix Settlement—where he, his wife, and three of his four children lived. Harilal, his oldest son, had stayed in England to study.

Ultimately, the £25 Tax was reduced to a £3 tax, rather than being rescinded, by the South African Parliament, which only served to increase Indian resentment. A new battle arose over a government order to register all Asians, including longtime residents as well as new immigrants, and women and children. This order, commonly known as the “Black Act,” also required fingerprinting. The entire community was outraged. This sparked Gandhi’s first campaign based on Satyagraha, or political struggle through passive resistance and civil disobedience. Many were arrested for their failure to comply with the order, including Gandhi, who was imprisoned for the first time. Eventually, Gandhi reached an agreement with Cabinet Minister Jan Christen Smuts, whereby the amendment would be repealed once most of the Indian population had registered.

Even after a show of Indian compliance, the South African government reneged on the agreement and in 1908 the Indian community met to burn their registration certificates. Once again, many were arrested, including Gandhi, who was sentenced to prison. In 1913, when the Cape Supreme Court ruled that any marriage outside Christianity and/or not recorded by the Registrar of Marriages was invalid, Indian women became involved in the demonstrations.

To goad the British into revoking their harsh requirements, Gandhi organized a “Great March” of 2,000 Indians from Natal into the Transvaal. Indians were bound by law to present registration papers at the point of entry, though Europeans were not so restricted. The march was meant to overcrowd prisons and increase pressure on the government to repeal the law. This situation deteriorated into such harsh conditions for the Indians that even members of the British government began to support Gandhi’s movement. Embarrassed, the South African government rescinded its order and the Satyagraha campaign in South Africa ended. Soon after, Gandhi returned to India for the rest of his life.

In 1915 Gandhi established the Satyagraha Ashram near Ahmedabad. At that time, Indian society was divided into a social hierarchy of four castes, with the Dalits or “untouchables” considered the lowest of the four. Those of higher castes were even bound not to touch them. Gandhi, who was adamant that all men were created equal and that the caste system should be abolished, was eager to admit an “untouchable” or Dalit family to his ashram. Despite such efforts, however, his continuing push to end the caste system had little result.

Gandhi practiced law in Bombay for a time, but was drawn into renewed Satyagraha for Indian social causes by people who had learned of his success in South Africa. At Champaran, he campaigned for the indigo workers and at Kheda, he pursued justice for factory workers who were being mistreated. When the British passed the Rowlett Act (1919), which gave them full authority to squelch “terrorist” demonstrations, Gandhi launched a series of marches and fasts known as hartals (“strikes”).

Violence marred the hartal in Delhi and an outright massacre took place at Jallianwala Bagh, leading Gandhi to call a halt to the strikes. Many of Gandhi’s followers were unhappy with this decision, which some saw as a sign of weakness. Muslims began to pull further away from the predominantly Hindu Indian population and to consider alternatives for themselves, such as an independent Pakistan. Gandhi could not sway them. Even his staunch supporters began to question his ability to lead the people.

But when the activist leader Bal Gangadhar Tilak died in 1920, Gandhi was called on to fill the void in the Home Rule movement, even as his health was failing. He called for a complete boycott of the legislature and proclaimed January 26, 1930, to be Purna Swaraj Day (“Total Independence Day”).

On March 2 Gandhi wrote to the viceroy, Lord Irwin, warning him that he intended to lead followers on a civil disobedience march to protest the prohibition against collecting salt naturally. Actions contrary to this law were harshly dealt with, but when Gandhi had no reply to his
ultimatum, the 200-mile march to the sea began on the morning of March 11. As the group traveled along, they stopped in villages and small towns, encouraging residents to burn all European cloth in their possession. Gandhi urged them to spin their own thread and to wear garments made only with Khadi, the homespun Indian material. When the throng reached the salt mines, Gandhi encouraged them to take up salt from the salt beds. Many people were assaulted by police and arrested. Gandhi was among those taken and imprisoned without trial.

In the ensuing months, more than 100,000 were arrested, and the upheaval continued until a pact aimed at ending the civil disobedience was made between Gandhi and Irwin. During the last four months of 1931, Gandhi attended a Round-Table Conference in London to discuss Indian issues with representatives of the British government. At the conference, the British offered to reserve a block of seats in a proposed bicameral legislature for Muslims, Sikhs, and Dalits. Gandhi was vehemently against this proposal because he thought that all Indians should be treated equally, and should not be divided into separate blocks. Though B. R. Ambedkar, the leading Dalit politician, tried to make Gandhi see that this was the Dalits’ only chance of representation, Gandhi continued to oppose the proposal and began a “fast to the death” to stop it.

Gandhi would endure several fasts, more imprisonment, and the deaths of his wife and personal secretary before a final agreement—the Indian Independence Act of 1947—was reached, granting full independence to India. This agreement also called for the creation of an independent Pakistan, a provision that upset many Muslims. Not all Muslims lived in northern India, where Pakistan was formed, and many were displeased that relatives would be living in another country. They felt that Gandhi had failed them. While holding a prayer meeting at Birla House in Delhi on January 20, 1948, Gandhi was murdered by an angry Muslim.

Gandhi, know as the “Mahatma” or the “Great Soul,” was at various times underestimated by the British and by Indian politicians. Though the latter had set him aside as an incompetent old man, they soon came to realize how much they needed him as a source of inspiration, because only Gandhi had been able to hold sway over the hearts and minds of the Indian people.

GANS, HERBERT J.

1927–

Herbert J. Gans was born in Cologne, Germany, in 1927. He escaped the worst of the Nazi Occupation, moving first to England in 1938 and then to the United States in 1940, becoming an American citizen in 1945. After graduating from the University of Chicago in 1950 with an MA in sociology and social science, Gans worked for three years with public and private agencies as a planner of two new towns. In 1953 he turned to academia, receiving his PhD from the University of Pennsylvania in 1957 and advancing to the position of associate professor of urban studies by 1964. Between 1964 and 1969, Gans worked as a research associate for the Institute for Urban Studies and Planning at the Massachusetts Institute of Technology. In 1971 he became a professor of sociology at Columbia University, and in 1985 he became the Robert S. Lynd Professor at Columbia. In 1989 he served as president of the American Sociological Association, and he received the association’s Public Understanding of Sociology Award in 1999.
Gans's research and teaching activities have been largely concentrated in the area of urban sociology. Committed to the social-scientific method of participant observation, his first book, *The Urban Villagers* (1962), was a study of an Italian American neighborhood in Boston. Gans noted how economic terms such as *underclass* had evolved into judgments of moral value attached to the poor in society. From his analysis, Gans concluded that the various forms of social problems associated with poor neighborhoods were not a cultural characteristic of the people who lived there, but rather a direct result of the social and economic circumstances of their poverty. This was to be a recurrent theme in Gans's writings, emerging powerfully in a later work, *The War against the Poor* (1995), in which he analyzed the social, psychological, and political reasons that Americans continue to seek to indict millions of poor citizens as “undeserving.”

*The Levittowners* (1967) focused specifically upon the origin and quality of suburban life, including its effects on human behavior. Gans then moved on to challenge the supposed universality of high cultural standards in *Popular Culture and High Culture* (1974). An outspoken advocate of cultural pluralism, Gans pointed out that the alleged convergence of high culture and popular culture could not be empirically sustained, because the lifestyle choices of middle-class and working-class social groups remained divergent. This concern with how various social groups make decisions informed his next publication, *Deciding What's News* (1979), in which he looked at the impact of news agendas on individual decision-making and the shaping of a nation's self-image. He returned to this theme in *Democracy and the News* (2003), arguing that a news media manipulated by private corporations threatens to undermine the basic foundations of American democracy by failing to properly inform its citizenry.

One of Gans's most influential concepts is “symbolic ethnicity,” which refers to a nostalgic allegiance to an ethnic culture, typically of an immigrant generation, that can be felt without having to be frequently incorporated into everyday life practices. Symbolic ethnicity is thus about feeling ethnic, without necessarily being so.

A second influential idea is the “function of poverty,” and Gans will be remembered for the controversy that this idea created. Gans argues that poverty satisfies a number of positive functions for many nonpoor groups in American society—such as carrying out the essential low-paid work that others will not undertake. Though he has controversially associated poverty with positive functions in this way, Gans maintains that recognizing this does not mean that poverty should, or must, continue to exist.

**GARIFUNA**

The population of people known as Garifuna, Black Carib, Charaib, and—as they refer to themselves in Belize, Central America—as *Garinagu*, is the product of ethnogenesis (a genetic and cultural mixture) resulting from the collision of the Atlantic slave trade, colonial settlement, and the region's aboriginal people. In the 1600s a cargo of slaves was shipwrecked off the coast of either Dominica and/or the Island of St. Vincent located in the Lesser Antilles of the Caribbean. These escapees found refuge among the aboriginal Carib Indians, and, over time, recruited others—mostly men—through raids of local plantations. This pattern of marronage produced a new group that populates Central America, specifically Honduras; Bluefield, Nicaragua; Livingston, Guatemala; and Belize. In 1974 William V. Davidson estimated the Garinagu population at 70,000 to 80,000 with the largest concentrations in the Honduras and Belize. In 1998 Mark Moberg placed the Garinagu population at 120,000. And in 2000, Pamela Conley estimated there were 200,000 people living in Honduras, with 15,000 and 6,000 residing in Belize and Guatemala respectively (Conley 2000). Smaller groups of a few thousand live in Nicaragua and the Windward Islands. Late-twentieth-century migration accounts for the presence of Garinagu in Brooklyn, Chicago, and Los Angeles.

The Garinagu's arrival to the coastal countries of Central America is a testimonial of group survival and what Moberg terms “their extraordinary adaptability” (1998, p. 1014). A hunter gatherer society, who were “fiercely independent” (1998, p. 1014), the British violently exiled them from the Island of St. Vincent in 1797 after intense military engagement that included the First Carib War (1772–1773) and the Second Carib War (1795–1796). Land disputes marred their relationship with the British, in stark contrast to their peaceful relationship with the French. At the end of the second war, the British, says anthropologist Joseph Palacio, “viciously
extricated … [Garinagu] men, women, and children from their hideouts” (Palacio 2000, p. 4). Approximately 4,338 people, who were not among those decimated during the final altercation, were temporarily held on the desolate island of Baliceaux before being exiled to Roatan in Central America. From Roatan, which the British clearly intended as a place for their demise, the Garifuna with Spanish assistance migrated to Honduras. In 1832 a small group left the (Spanish) Honduras for Belize (formerly the British Honduras). What has emerged from this interaction of African and aboriginal Arawak/Carib Indians is an adaptive group with several unique cultural characteristics.

LANGUAGE
Garinagu speak the gendered language of Garifuna with different dialects for men and women, an aspect reflective of the social ecology of the Island of St. Vincent, whereby “Red” Caribs appropriated Arawak women as war prizes and intermarried with them—with women preserving their Arawak dialect. In the early twenty-first century the language retains this distinctive gender feature and reflects both African and aboriginal Arawak/Carib Indian influences. Garinagu are noted in the region for their “linguistic versatility,” and are often fluent in multiple languages (Garifuna, Spanish, English [in Belize], and indigenous Maya languages). This multilingualism has translated itself into professional capital, with many becoming educators and teachers, especially in the rural (Maya) areas of Central America.

CULTURE
Palacio describes Garinagu as an anomaly because of the amalgamation of aboriginal cultural traits and African cultural survivals (2000, p. 2). Garifuna myth and folklore reveal strong aboriginal Indian components while diet reflects many West Indian Afro-American food ways. Historically reliant on a subsistence lifestyle, cassava carries symbolic significance as a diet staple, and as the food that enabled Garinagu to survive exile. Cassava is especially important to the dügü ceremony, a sacred religious ritual used to appease dead ancestors after a family experiences a difficult period; all relatives are required to attend the dügü, a communal event designed to reestablish spiritual, physical, and social equilibrium. Contemporary Garinagu religious practices reflect the syncretism of African ancestor worship and Roman Catholic beliefs.

GARINAGU TODAY
With the exception of Belize, Garinagu remain politically and economically marginalized in most of the countries where they reside. A reputation for resistance caused British colonial administrators to separate them from other colonized groups of Blacks—a divide and conquer strategy that in the twenty-first century translates into ethnic tensions between Garinagu and other African-descended populations; for example, in Belize, there is very little intermarriage between African-descended Creoles and Garinagu. The group’s strong African phenotype caused some to question the validity of their claims of aboriginal ancestry. However, in 1992 they applied for membership within the Ottawa-based World Council for Indigenous Peoples and were accepted. Preservation of the Garinagu cultural heritage, especially language and the dügü ritual, as well as the struggle for land rights, continues to be a priority. The pervasiveness of the punta, however, throughout Central America, a dance derived from the dügü, attests to the ways in which even marginalized cultures have an impact on the larger societies.

Irma McClaurin
GARVEY, MARCUS
1887–1940

Marcus Garvey was the founder of the Universal Negro Improvement Association and African Communities League (UNIA). He was a prominent spokesman for the “back to Africa” movement within black nationalism, which urged people of African ancestry to return to the continent. He is revered as a prophet in Rastafarianism.

Garvey was born in Jamaica and traveled to London and the United States before World War I (1914–1918). He started the UNIA in Jamaica in 1914 as a fraternal organization calling for self-improvement for poor Jamaicans. As the movement took on a more political character in the 1920s, it gathered support from earlier movements for black liberation in the colony, such as the nineteenth-century ex-slaves reparations movement. Garvey corresponded with Booker T. Washington, who had called for black economic self-sufficiency in his Atlanta Address of 1895, and in the early days of his movement shared Washington's gradualist approach.

When Garvey went to the United States in 1916, his hope was to emulate Booker T. Washington by starting a school in Jamaica to train poor blacks in practical subjects. Once in America, however, he established a branch of the UNIA there, and in the end it was in North America that the movement had its greatest membership and influence in the period after World War I.

The purpose of the UNIA as Garvey expounded it in the period between 1918 and 1922 was to unite blacks around the world and to work for independent economic improvement. He was not a black supremacist, but instead believed that the races would prosper best if they were separate and self-sufficient. Garvey gathered support from veterans of previous black campaigns, especially the movement for pensions for slaves that had been led by Callie House. Garvey provoked controversy when he lent support to President Harding's campaign against miscegenation and he was arrested. He finally left Jamaica in 1935 but was harshly critical of Emperor Haile Selassie after Ethiopia's surrender in 1936 (a fact often overlooked by Rastafarians, for whom Selassie is a divine figure).

In order to put his philosophy of racial self-sufficiency and self-redemption into practice, Garvey founded a number of businesses. Most famous were the Black Star shipping line and the Negro Factories Corporation. Unfortunately, the realities of the business climate in the 1920s, colonial regulations in Africa, and American racial discrimination meant that his businesses were unsuccessful. After the failure of the Black Star Line, the American Department of Justice, spurred on by the new director of the FBI, J. Edgar Hoover, brought charges of fraud against Garvey. The charges hinged on a technicality—whether the Black Star Line had ever owned a ship depicted in the stock prospectus. It is still unclear to this day whether Garvey actually did anything wrong. Nonetheless, there had certainly been a lot of shaky financial deal-making in the company's history, and Garvey, if not guilty himself of participation, had at least overlooked some misdeeds. In any case, a black nationalist found it difficult to get a fair trial in 1920s America. Garvey was imprisoned for several years, before President Coolidge commuted his sentence. He was deported to Jamaica in 1927.

Garvey had a long dispute with black civil rights leader W. E. B. Du Bois. Du Bois argued in the early part of the twentieth century that American blacks should work to integrate public institutions and call upon the U.S. government to live up to the high standards of equal treatment under law enshrined in the Constitution. He was one of the founders of the National Association for the Advancement of Colored People (NAACP), which played a key role in the struggle for racial integration and civil rights for American blacks. Du Bois's position was, of course, diametrically opposed to Garvey's. To Garvey, racial integration was at best an illusion and at worst a snare to keep blacks subordinate to whites and away from their destiny in Africa. Their dispute took on an unfortunate personal tone, with Du Bois calling Garvey a "lunatic" and Garvey responding that Du Bois was a "white man's nigger" and a "mulatto monstrosity." Ironically, Du Bois later came to a position closer to that of Garvey than to his former integrationist stand, and himself emigrated to Africa, dying a Ghanaian citizen.

After his return to Jamaica, Garvey formed the People's Political Party (PPP), the first modern political party in Jamaica. Up to this time, Garvey had been reluctant to get involved in politics, seeing the political system as irredeemably white-dominated and participation a form of tokenism that could distract blacks from self-sufficient development. Garvey was elected twice to town council seats, but his views annoyed the colonial government and he was arrested. He finally left Jamaica in 1935 and spent the last five years of his life in London, continuing to work toward his vision of black self-sufficiency and African liberation, but with limited results.
Garvey’s movement, although manifesting itself under a variety of different names and somewhat different ideological colors in its several homes, can be considered the first international African movement and perhaps the most dynamic force in the struggle for democracy, dignity, and human rights for black people of the first half of the twentieth century. Garvey deserves a place alongside better-known figures such as Martin Luther King Jr., Du Bois, Frederick Douglass, Sojourner Truth, and Toussaint Louverture as a hero in the struggle for black liberation in the Americas.

Garvey’s remains were moved from London to Jamaica in 1964 and were buried in the national heroes’ cemetery in Kingston. He is venerated today as a founding figure in Jamaica’s struggle for national liberation.

Garvey’s own religious practices were conventional—he was a Roman Catholic—and he never claimed any religious authority. However, the Rastafarian movement has adopted him as a major prophet, with many Rastas seeing him as the reincarnation of John the Baptist, Moses, or Elijah. Indeed, the modern Rastafarian movement sprang up after the collapse of the UNIA and the PPP and incorporated many members of those organizations. Garvey’s project of returning blacks to Africa is a centerpiece of most Rastafarian theology. Of course, for Rastafarians, it is a religious duty to return Jah’s people to the promised land, while for Garvey it was a practical necessity.

GAUTREAUX RESIDENTIAL MOBILITY PROGRAM

The result of a 1976 Supreme Court decision, the Gautreaux program allowed low-income black public housing residents in Chicago to receive Section 8 housing certificates (vouchers) and move to private-sector apartments either in mostly white suburbs or the city. Between 1976 and 1998 over 7,000 families participated. The Gautreaux program presents an unusual opportunity to examine the outcomes associated with low-income families’ moves to more advanced neighborhoods with better labor markets and schools. Most research on neighborhood effects has focused on statistical analyses of the relationship between neighborhood attributes and many life outcomes. However, even after extensive statistical controls, one cannot be certain about the direction of causality or whether unmeasured factors might influence relationships. Housing mobility programs such as Gautreaux are one way to separate these effects.

Gautreaux participants circumvented the typical barriers to living in suburbs, not by their jobs, finances, or values, but by acceptance into the program and quasi-random assignment to the suburbs. The program provided housing subsidy vouchers, but not employment or transportation assistance. Unlike the usual case of working-class blacks living in working-class suburbs, Gautreaux permitted low-income blacks to live in middle-income white suburbs. Participants moved to more than 115 suburbs throughout the 6 counties surrounding Chicago. Suburbs with a population over 30 percent black were excluded. Few high-rent suburbs were excluded by funding limitations of Section 8 certificates.

Prior research on Gautreaux shows significant relationships between placement neighborhoods and subsequent employment and education. A study of children finds that, as young adults, suburb movers were more likely than city movers to graduate from high school, attend college, attend four-year colleges (versus two-year colleges), and (if they were not in college) to be employed and to have jobs with better pay and with benefits (Rosenbaum 1995). A study of 330 Gautreaux mothers finds that suburban movers had higher employment than city movers, but not higher earnings, and the employment difference was especially large for adults who were unemployed before the program (Rosenbaum 1995). Using
administrative data to locate present addresses for 1,504 out of 1,507 movers, research finds that 65 percent of suburban families remained in the suburbs an average of fourteen years after placement. After premove individual and neighborhood attributes were controlled, program placement strongly predicted racial composition of current neighborhood (DeLuca and Rosenbaum 2003) and public aid receipt many years after moving (DeLuca and Rosenbaum 2003; Keels et al. 2005).

Because researchers had no input into implementation, families were not formally randomly assigned to conditions. However, placements approximate random assignment, because families were assigned to neighborhoods on a first-come, first-placed basis (according to reports of housing counselors and administrators in the 1980s). Few significant differences were evident with individual attributes, but premove neighborhood attributes show statistically significant differences (2 of 9 comparisons). This may indicate selection bias, although even random assignment programs find some substantial differences (Goering and Feins 2003, table 7.1). Other studies have examined multiple neighborhood level indicators, detailed preprogram neighborhood differences, and intergenerational effects (DeLuca 2006).

Based on Gautreaux, the Moving to Opportunity program (MTO) was an experiment with pre- and post-move data and random assignment of low-income families to three groups—one required to move to low-poverty areas, one with open-choice use of housing vouchers, or a control group given no vouchers. Like Gautreaux, MTO found large effects on mothers’ and children’s feelings of safety and other attitudes. MTO also found large effects on mothers’ and daughters’ health.

MTO had smaller effects on mothers’ employment and children’s education than Gautreaux. However, MTO measured outcomes in the late 1990s, during a strong labor market and strong welfare reform, so, although MTO found no difference between groups, it found an astounding 100 percent employment gain for the control group. One possible interpretation is that virtually everyone who could work was doing so, and residential moves had no additional effect for that reason.

Program attributes may explain other findings. While few MTO children attended schools with above-average achievement, nearly all Gautreaux children did. While families made short moves that allowed interaction with prior neighbors (only 16% of moves over 10 miles), Gautreaux’s distant moves (90% over 10 miles; average 25 miles) prevented such interaction. While Gautreaux families moved to stronger labor markets, MTO treatment group moves were not necessarily to different labor markets.

The Gautreaux studies suggest the possibility that large changes of environment can have large impact. The MTO results do not contradict that lesson; few MTO moves entail distant moves to above-average schools or much better labor markets. However, MTO research provides strong evidence about modest changes of environment. While both studies indicate enormous effects of residential moves, the differences between the findings indicate the importance of being alert to design features of the program and to historical context influences.

GAZE, COLONIAL
Modern colonial rule relied not only on the military and economic power of conquering nations, but also on domination over forms of cultural representation. The period
of Europe's political expansion, starting in the late fifteenth century, witnessed the development of significant new cultural technologies. From the printing press to photography, film, and sound recording, technical innovations enabled novel ways of documenting and disseminating knowledge about Europe's encounters with the non-Western world. Through newspapers, travelogues, popular magazines, and documentary films, European officials and travelers made images of distant colonial settings available to larger, more diverse metropolitan audiences. While such work rapidly expanded knowledge about hitherto remote regions, it was frequently riddled with stereotypes and assumptions that classified societies according to Eurocentric hierarchies. The power to represent colonized populations played an integral role in their subjugation, as narratives of backwardness and primitivity were essential elements in the justification of colonial rule.

Modern colonialism possessed a particularly ocular character, and based its ruling practices on the development of novel conventions for viewing and representing conquered lands. The earliest encounters of Europeans with Native Americans of the New World, for instance, produced an entirely new popular genre of eyewitness travel writing. In contrast to older speculative geographies, the credibility of such early ethnographic work derived from the firsthand nature of the accounts. Many were sensationalistic survival-adventure narratives that featured voyeuristic descriptions of primitive, foreign societies, with their colorful native costumes and spectacular rituals. Not coincidentally, this was also a period when modern techniques of observation and verification were reshaping claims to scientific authority in other fields. Breakthroughs in the study of optics and new scientific procedures for conducting experiments had emphasized the importance of visual evidence, and the accurate representation of observed phenomena. Valued for their observational insights, colonial travelogues often gained both scientific and commercial success. Many became best-selling publications and were reissued and translated into numerous different European languages.

Travelers' descriptions of colonial encounters helped European readers imagine the rest of the globe, and their place within it. By the early sixteenth century, images and descriptions of faraway places could be enjoyed, as vicarious journeys, directly from one's location in the metropole. Travelogues were frequently valued for their accompanying illustrations, as much as for the narrative descriptions of exotic cultures. For many sixteenth- and seventeenth-century readers, the New World was first made familiar through the engraved illustrations of the Dutch publisher, Theodor de Bry (1528–1598). While some of these representations, including his famous woodcut prints of ritual cannibalism in South America, might today be dismissed as sensationalistic distortions, images of faraway people and places helped to structure the wider social imagination of the early modern European public. By representing the non-European "other" as a definable object of visual scrutiny, such work also helped Europeans establish a sense of cultural and scientific supremacy within an emerging global order. Such a planetary consciousness, as literary theorist Mary Louise Pratt (1992) has argued, helped direct and organize colonial expansion. Just as the iconic images of National Geographic helped define American political and social sensibilities in the middle of the twentieth century, early modern Europeans understood their role in the world through the production and consumptions of such images. It helped them imagine both the unity and the fault lines of a globe that was growing ever smaller through trade, discovery, and conquest.

By the eighteenth and nineteenth centuries, images of non-European societies had spilled over from the pages of print media into new forms of visual display. The Great Exhibitions, for instance, attempted to reproduce distant parts of the globe in painstaking detail. European audiences imagined that they were in fact walking through the bazaars and alleyways of Egypt or India, all for the price of an entrance ticket. Putting the world on display served not only to represent cultural differences, but also worked to define them and turn them into objects of modern consumption. Such displays, through world fairs, museums, and travel brochures, determined the way that the non-West was perceived by both casual visitors and colonial officials. The bird's-eye view employed in book illustrations, postcards, and travel guides was frequently reproduced in the work of official colonial cartographers. Such conventions for viewing and representing colonial people and places formed part of a formal repertoire, used by official cartographers and surveyors to demarcate boundaries, to catalog monuments, and to assist ethnologists and criminologists in categorizing racial types in the colonies. Documentary photography later replaced hand-drawn illustrations as a popular method of recording and classifying data on the architectural and social features of the colonies. Such documentation, in attempting to make the colonies legible to metropolitan observers, fixed and naturalized complicated social boundaries, and opened these up as sites of official intervention.

European practices for viewing and representing colonial realities often made social differences more rigid, and exacerbated racial and gender hierarchies. The colonial gaze played a singularly important role in defining gender relations by marking out colonial women as objects of particular interest, either as targets of official sympathy or casual lust. Harems, zenanas, and veiled women figured prominently in European accounts. Colonial officials also paid particular attention to social rituals associated with female oppression, such as sati (rit-
ual suicide by Hindu widows), the wearing of the veil, and foot binding. While these practices were condemned, they remained subjects of fascination, and frequently found their way into travel accounts and novels set in colonial contexts.

Similarly, racial distinctions are also reproduced and enforced by the colonial gaze. Frantz Fanon (1925–1961), a psychologist and volunteer during the Algerian Revolution (1954–1962), in his semiautobiographical critical work *Black Skin, White Masks* (1952), writes about the psychical trauma of being identified as an object of the white gaze. Robbed of the possibility of being a full-fledged modern subject, a person of color is determined from the outside, as a thing, an object of scrutiny. The colonial gaze, determined by a set of technologies and conventions for viewing colonial realities, underwrote colonial power. It turned people into observed objects, and authorized the official discourses of European viewers, whose representations determined and fixed the status and stature of colonized subjects.

**GAZE, PANOPTIC**

The concepts of panopticon and panoptic gaze can be traced to the 1791 publication of Jeremy Bentham's *Panopticon; or, The Inspection House* (Bentham 1962, p. 37). Although he presented it primarily as a prison design, Bentham (1748–1832) believed the panoptic principle was "applicable to any sort of establishment, in which persons of any description are to be kept under inspection," including prisons, workhouses, manufactories, hospitals, and schools (vol. 4, p. 37). Bentham asserted that "gradual adoption and diversified application" of this "simple idea in architecture" would have far-reaching benefits: "morals reformed, health preserved, industry invigorated, instruction diffused, public burdens lightened ..." (vol. 4, p. 66).

The ideal panopticon consists of an observation tower within a large circular courtyard ringed by a cell-block several stories high but only one room deep. Each cell should be occupied by only one surveillant who is subject to constant observation from the tower; yet, the design of the panopticon simultaneously prevents communication between inmates. Ideally, the central tower is screened, so the inmates never know who (if anyone) is in the observatory at any particular time.

According to Michel Foucault’s analysis of panopticism in *Discipline and Punish* (1979), this design has a number of effects. Because the observer is screened from the gaze of the inmates, the see/being-seen dyad is dissociated, inducing “in the inmates a state of consciousness and permanent visibility that assures the automatic functioning of power” (p. 201). Furthermore, the exercise of power is dispersed, depersonalized, and internalized by the inmates. Who, if anyone, actually occupies the tower is irrelevant to the functioning of the mechanism, so long as the inmates (or patients, students, workers, shoppers) behave as if they were under constant surveillance. “[In short], the inmates should be caught up in a power situation of which they are themselves the bearers” (p. 201). Although the panopticon in its pure and literal form was relatively rare, it was—and remains—an extremely pervasive “political technology that may and must be detached from any specific use” (p. 205).

Investigators in disparate social science fields have noted the importance of panoptic surveillance in both historic and contemporary contexts. For example, Thomas Jefferson was quite familiar with Bentham’s work and utilized panoptic principles in the design of Monticello, his hilltop estate. He subsequently drew on French examples of panoptic institutions in his plan (never implemented) for a prison to be constructed in Richmond, Virginia (Epperson 2000; Upton 1990). Similarly, James Delle (1998) has analyzed the importance of the panoptic gaze in the spatial disciplining of enslaved plantation workers in Jamaica, and Mark Leone (1995) has discerned panoptic principles in city plans and public architecture in Annapolis and Baltimore, Maryland. According to urban geographer Edward Soja, “every city is to some degree a panoptic, a collection of surveillant nodes designed to impose and maintain a particular model of conduct and disciplined adherence on its inhabitants” (1996, p. 235). In contemporary Los Angeles the panoptic gaze is manifested architecturally in disciplinary institutions such as the Metropolitan Detention Center and electronically in closed-circuit surveillance cameras (Davis 1992; Soja 1996).

GAZE, THE

Until the nineteenth century, philosophical inquiry into the question of visionality mainly concerned matters of sense perception, the nature of imagination, and the truth-status of representations. A long tradition in western and many nonwestern philosophical discourses gives to vision a particular and relative significance as the medium of both apprehending the world and verifying the truth of predicative statements. Beginning in the seventeenth century, however, scientific inquiries into the mechanics of perception, and post-Cartesian investigations of the relationship between mind and body, led to a split in discourse about visuality. That split was oriented around the opposition between “seeing” and “being seen,” and between the “eye” and the “gaze.”

There have been a number of efforts to historicize this process, most notably by Michel Foucault, Jonathan Crary, and Martin Jay—the first in the realm of knowledge, the second in the realm of technology, the third in the domain of aesthetics. Despite their different disciplinary locations, these authors all undertake a twofold gesture. First, they trace the impact of optics and the development of associated technologies, noting that efforts to augment and extend the reach of vision (via the microscope, the telescope, and so forth) were associated with the idea that reality is limited to that which can be brought into the field of vision. Second, and simultaneously, they emphasize that these historical and technological developments made palpable the limits of the human eye as an organ for discerning reality.

Martin Heidegger had criticized the simultaneous valorization of technology and the limitation of human faculties to a practice of organizing the world for vision in his essay “The Age of the World Picture” (1952), but his philosophical intuition was not supported by historical research. In the writings of Michel Foucault, however, the historicization of vision is linked to an analysis of emerging forms of governance in the western polities.

Foucault identified a form of governamentalty dominated by the logics of surveillance, which, he argued, were sustained by the discourses of institutionalized knowledge, from clinical medicine to geography, education, and psychology. In Discipline and Punish (1977), for example, Foucault states that penal architecture and social reform converged in the post-Enlightenment period around a new aim: the cultivation of a political subject who would internalize and anticipate the “gaze” of power. This new structure of subjectification, Foucault argues, was not only marked by a normative demand for self-discipline but was also associated with the depersonalization of power. As a result, power became a force no longer incarnated in the relatively sovereign body of the monarch, but one that was diffused through a vast capillary system of microinstitutions. Taken together, this system worked to generalize the sensation of being seen, precisely in the moment that overt spectacles of power lost their centrality; thus did a theater of power in which sovereignty showed itself as a local and even personal phenomenon give way to an unconscious and invisible dramaturgy that demanded the self-revelation of subjects. In many ways, Foucault’s history of power’s depersonalization resonates with Max Weber’s conception of bureaucratization, but for Foucault the process was dependent on the relative privilege that vision enjoyed in the discourses of power and knowledge.

Foucault’s writings entered a field in French philosophy that was equally concerned with the concept of “the gaze” (le regard). In the existentialist thought of Jean-Paul Sartre and the structural Marxism of Louis Althusser, the gaze features as a structure of negative identification. In strikingly analogous scenarios, these writers describe moments when a figure of power discovers the subject, often in some illicit act such as peeping through a keyhole or committing a crime. In Sartre’s case, this moment of being discovered produces shame; in Althusser’s case, it is followed by the subject’s being “hailed” by the representa-
tive of power, a process that grants him (or her) a violent kind of recognition. Both cases express a sense of subjunctification as that which takes place in and through the experience of being apprehended in the visual domain. Significantly, this “being seen” occurs from a point unseen by the subject.

This concept of the gaze is further developed in Jacques Lacan’s famous seminar XI of 1964. However, Lacan revised this notion of the gaze as the condition of “being seen” by positing a prior state of “giving to be seen.” Lacan’s particular interventions responded to the writings of Maurice Merleau-Ponty, whom Lacan credits with the basic understanding that human subjects apprehend the world from the position of visceral materiality: as objects among other objects. According to Merleau-Ponty, what makes human beings exceptional is that they orient themselves to those other objects, and he calls this orientation intentionality. Moreover, in Merleau-Ponty’s analysis, intentionality is organized by the perception of form, and by the imagination of an all-seeing being behind the myriad objects that constitute the world.

Lacan insists that this all-seer is merely metaphorical, the name of a principle by which the visible is actually dependent on a structure that places the subject under the gaze of an “other.” But this gaze of the other is also a metaphor in Lacan’s writing, or rather it designates the process by which the subject covers over the fact of the gaze’s invisibility with an image of a seer’s eye. This misrecognition is necessary, argues Lacan, if the subject is to feel attracted to or aroused by desire. Here, desire designates a lack in the subject, and this sensation of lack is what compels the subject toward intimate social relationships, but also, as later thinkers such as Judith Butler have reminded us, toward normative forms of identification. This normative dimension of the gaze is not lost on Lacan, and he notes that, in patriarchal contexts, this “giving to be seen” is realized and demanded most especially of women.

Frantz Fanon had, in fact, already discerned the unequal distribution of the effects of the gaze in his reading of the experience of being looked at as a “negro.” Fanon emphasizes the nonreciprocity of looks in colonial milieux, noting that only racially dominant subjects can appropriate the power that is located in the gaze, whereas black subjects must constantly give themselves to be seen in a process that renders them vulnerable to catastrophic psychic injury. Although this appropriation is itself born of a misrecognition or conflation of eye with gaze, it is nonetheless one that is withheld from black subjects under colonial conditions, according to Fanon.

It is often assumed that Lacan’s theory of the gaze represents the apogee of a tradition that renders the question of the subject a matter only of ontology. By contrast, Foucault’s reading of the gaze is said to represent an absolute historicization of the concept, and a repudiation of ontological arguments. To be sure, Foucault’s historicist critique of psychoanalysis encouraged the reading of their approaches to the question as mutually exclusive. It is important to recognize that Lacan himself undertook his analysis of the gaze with an explicit invocation of the Cartesian turn in philosophy and with a nod to the representational histories that precede and follow upon it in the plastic arts. It therefore may be more helpful to understand these two thinkers, and the approaches that they inaugurated, as symptoms and diagnoses of a persisting moment lived in thrill of vision’s hegemony. Foucault approaches the question of the gaze from the point of view of what he calls “human multiplicities,” whereas Lacan treats the subject who, precisely, possesses a “point of view” rather than a gaze.

It is nonetheless notable that this development of theories about the gaze occurred in the space between World War I and the conclusion of the space race toward the end of the 1960s. In other words, the problematization of the gaze occurred in the moment that European modernity seemed to be in ruins thanks to the experience of aerial warfare (in which oversight had made total destruction possible), and, simultaneously, on the brink of a new kind of total visibility made possible by space travel, satellite imaging, and the first experience of earth as apprehended from elsewhere. In France, where most of this work was generated, the exposure of rationalism’s apotheosis in the death camps of World War II was followed by the revelation that Soviet socialism had become a totalized penal society, and together these spurred a massive rethinking of both sovereignty and subjectivity. It is in this nexus that the question of the gaze itself becomes visible.

GEERTZ, CLIFFORD

1926–2006

The American cultural anthropologist Clifford Geertz was known for contending that culture is the enacted and public creation of meaning and that therefore ethnographic inquiry requires interpretation. Drawing on extensive fieldwork in Indonesia and Morocco, Geertz’s theory of “interpretive anthropology” was articulated in his 1973 collection, The Interpretation of Cultures, in which he stated, “The concept of culture I espouse … is essentially a semiotic one. Believing, with Max Weber, that man is an animal suspended in webs of significance he himself has spun, I take culture to be those webs, and the analysis of it to be therefore not an experimental science in search of law but an interpretive one in search of meaning” (p. 5).

This search, Geertz noted thirty years later, involved “ferreting out the singularities of other peoples’ ways of life....” (2000, p. xi). Geertz emphasized the particularistic nature of cultural experience, highlighting the explanatory priority of symbols and attending to “local knowledge.” While sharing the American anthropologist Franz Boas’s goal of viewing cultures within their specific contexts, Geertz specifically focused on the cultural creation of symbolic meaning.

Geertz pursued graduate studies in the 1950s in Harvard University’s interdisciplinary Department of Social Relations and conducted ethnographic research in Java, receiving his Ph.D. in 1956. After a postdoctorate stint at the Center for Advanced Study in the Behavioral Sciences (1958–1959) and a year teaching at the University of California at Berkeley (1959–1960), Geertz joined the University of Chicago where he taught for a decade (1960–1970) and participated in the Committee for Comparative Studies of New Nations. In 1970 he joined the Institute for Advanced Study at Princeton, retiring as professor emeritus in 2000. A fellow of the National Academy of Sciences, the American Academy of Arts and Sciences, and other academic societies, Geertz penned Works and Lives: The Anthropologist as Author (1988) for which he was named the 1989 winner of the National Book Critics Circle Award for literary criticism.

Geertz’s thinking about interpretive ethnography was foreshadowed in the final chapter of The Social History of an Indonesian Town in which he outlined, following Harold Garfinkel, “the document approach.” In this approach, a specific ethnographic case is analyzed such that “the ineradicable specificity of actual events and the elusive generality of meaningful form render one another intelligible” (p. 154).

Having documented the event, it is the anthropologist’s task to decipher and expose its meanings. This requires interpretation. In The Interpretation of Cultures, Geertz argued that the ethnographer “must contrive to somehow first to grasp and then to render” the multiple conceptual structures that account for the meanings of cultural acts (p. 10). “An acted, public document” culture is “written not in conventionalized graphs of sound but in transient examples of shaped behavior” (p. 10). The anthropologist’s goals are to sort through “the structures of signification” that make such behaviors meaning-full, to decipher those connections in an ethnographic text, and to thus enlarge the consultable record of human experience.

Several objections can be raised to Geertz’s theory of interpretive anthropology. First, Geertz’s position is idealist, contending that culturally mediated concepts shape human behavior rather than, for example, the material conditions of existence. Second, the interpretive approach leads to several problems of method and validation. For example, how is one to think about the “structures of sig-

Rosalind C. Morris
nification”? Are some structures more central and durable than others, and in what contexts are they deployed? Explicitly focused on the microcosm, how can an interpretive approach address broader connections of history, economy, and power? Third, interpretive approaches are designed "not to generalize across cases but to generalize within them" (Geertz 1973, p. 26), thus precluding cross-cultural comparative studies. Finally, as Geertz acknowledged, interpretive accounts "escape systematic modes of assessment"; how can any interpretation be proven false? (p. 24).

Geertz’s interpretive anthropology departed from the paradigm of anthropology as a science in search of lawlike generalizations about humanity. From the 1970s to the present, the unbridgeable differences between interpretive versus scientific theoretical positions have crystallized into deep divisions within American anthropology.

GEMEINSCHAFT AND GESELLSCHAFT

In Gemeinschaft und Gesellschaft (community and society) by Ferdinand Toennies (1855–1936), the former refers to “all intimate, private, and exclusive living together,” whereas the latter is “public life—it is the world itself” (1955, pp. 37–38). The book contains an elaborate architecture of classifications covering the whole of social reality, from kinship to the modern metropolis. One of the most striking features of this is the way Toennies based his social forms on types of the human will: Wesenwille and Wesenwille, the will that directs thought (natural will) and the will that is subject to it (rational will). The relevance is evident, of calculation of means and ends to articulated purposes, to exchange relations of the Gesellschaft type. So, too, is the “natural” basis of the Wesenwille in drives, instincts, and emotions. Wesenwille is seen predominantly in Gemeinschaft forms.

The outward forms of the Gemeinschaft are the house, the village, and the country town, its general form the people (Volk). Gesellschaft is to be found in the larger cities. Its general form is the nation-state. Toennies stressed that his concepts were “types,” not classifications of the concrete. Reality always showed a mixture of elements. Nonetheless, Toennies also implied at one stage an evolutionary scheme in which Gesellschaft is seen as a temporary phase, Gemeinschaft returning on a higher level in an international socialist order of the future. Each type showed gradations of natural will and rational will—for example, in Gemeinschaft, kin, neighbor, and friend relations—so that natural will does not equate to emotion, drives, and instinct. Toennies’s point was that whereas the first is real and natural, the second is “ideal and artificial,” just as Gemeinschaft is real and organic life, the essence of community, and Gesellschaft is ideal and mechanical structure, the concept of society. Gemeinschaft is an original unity of will, Gesellschaft its individualized forms. Disintegration is built into Gesellschaft. It is checked by convention, agreement, politics, and public debate.

Robert Redfield (1857–1958) in his folk-urban typology (or continuum) spelled out Gemeinschaft and Gesellschaft in a more direct and usable way than Toennies, enriching and supporting it with current ethnographic evidence (1930). Howard Becker (b. 1928) in his sacred and secular societal types broke down Gemeinschaft and Gesellschaft into a set of subtypes, again with a view to making them more empirically flexible, and again enriching the basic pairing from evidence not available to Toennies. Robert E. Park (1864–1940) and the Chicago school took the role of place or locality as being central to Gemeinschaft and Gesellschaft. It was so for Toennies. This was because Gemeinschaft-type relations require enduring physical proximity as their condition. They used the the-
ory of ecology, suggesting that all living organisms are shaped in their relations by the physical environment, to study the city as a series of concentric areas or zones, each having their characteristic associational and cultural forms, and succession being visible as groups moved out of a zone and others moved in to replace them. Gemeinschaft and Gesellschaft can, finally, be treated as types of social relationship. Toennies was used this way by Max Weber (1865–1920), and Talcott Parsons (1902–1979) also read him for clues about the possible orientations of social action. Hermann Schmalenbach (1885–1950) added the important category “communion.”

Toennies has fallen into the background since the 1930s. For example, the importance of community as place rather than as social relations was challenged by Herbert Gans in his studies of community ties in suburbia, particularly in *The Levittowners* (1967). Nevertheless, Toennies’s place in the canon is secure: Gemeinschaft and Gesellschaft are basic categories. They may be approached on the level of our own experience.

In a Gesellschaft everything is clearly spelled out, so that everyone has clearly defined rights. If anyone asks us to go beyond our duties then they must give a reason, demonstrating why this extra demand is part of our “job description.” Only when this is demonstrated are we obligated to take on something further. In a Gemeinschaft the opposite is the case. We feel we cannot say “no” to virtually any demand. Indeed, it would not occur to us to assess the demand as a demand. This kind of calculation does not enter the picture. Here the burden of proof is on us to say why we should not respond positively, and if we feel we cannot, there will be a great deal of inner struggle. In a “full” Gemeinschaft this inner struggle does not occur at all, and we unreflectingly meet our obligation. Here, then, people make demands that are “total.” As today with a close family member, we are bound to them “come what may,” “for better or worse,” because the love involved is unconditional. No matter what the other person has done, irrespective of whether we feel drawn to them on a personal level—one might not feel “close,” or that the parties like and understand one another—the obligation is there. The other person does not have to have earned our trust and affection for the aid and assistance to be forthcoming. Here we have no escape from our duty, for example as a parent or as a child.

In a Gesellschaft it is the performance of a contractual obligation that matters. Whether it is done willingly or grudgingly, with affection or calculatingly, makes no difference. All that matters is that the contract is fulfilled to the letter, for example that the goods are delivered. In a Gemeinschaft how things are done is of interest. It matters, for example, that food is served in the family setting with love (though the food may be burned); it is the care that goes into the act that is at least as important as the act itself. It matters that the gift is carefully wrapped, showing that the giver has taken trouble.

These considerations show that Toennies’s original distinction has lost none of its relevance over the years. The problem of what makes us human, under what conditions people and their culture can thrive, and what in our culture threatens, as anomie, the mass society or latterly, “disembedding” and globalization, the nurturing, solidarity-generating, direct, sustained and deep contact between human beings, is a continuing one. It is both a public issue and a sociological question.

**GENDER**

In *The Second Sex* (first published in 1949), the French feminist Simone de Beauvoir led the way in distinguishing biological anatomy and chemistry from socialized gendered expectations: “One is not born but rather becomes a woman” (de Beauvoir 1953, p. 249). For de Beauvoir, being a female did not constitute being a woman. Rather, one’s biological makeup is subscribed with a social-cultural shaping of one’s gendered characteristics; for women this is the development of appropriate feminine behaviors. Though the term is highly contested and laden with political implications, at its most basic level gender is used to describe socially constructed characteristics of masculinity and femininity, whereas sex is used to describe one’s biological makeup (chromosomes, hormones, and reproductive/sexual anatomy).
THE SECOND-WAVE FEMINIST MOVEMENT

The distinction between sex and gender was an essential element for many issues addressed during the second-wave feminist movement (1960–1995). Though immensely diverse, many feminist schools of thought did agree that characteristics associated with femininity in the United States created norms and roles that oppressed women by limiting their access to public space and economic opportunities. Discussions of gender during the second-wave feminist movement often attempted to overturn what the scholar Harold Garfinkel described as the “natural attitude” towards gender (1967, p. 122)—the common belief that the gender dichotomy is a natural distinction between the two sexes. This assumption, according to activists, perpetuated inequality for women. In understanding the creation of the natural attitude, many feminists turned to the structure of the family and women’s connection to childbearing. Woman’s biological ability to give birth, combined with industrial changes, had led to social expectations of woman as nurturer, domestic caretaker, and other roles traditionally associated with the private sphere. Dichotomously, man’s inability to give birth and his larger physical makeup had led to social expectations to fulfill the role of protector, provider, and roles traditionally associated with the public sphere.

For feminists, these gendered characteristics, complicated by an array of other factors, had perpetuated a division of labor that empowered men and disempowered women. Men’s more active and dominant roles created an unequal relationship between the sexes that gave rise to an oppressive ideology both within the home and, more broadly, within institutionalized sexism. Overall, the most prominent goal of the second-wave feminist movement was to bring about a sense of gender equality. Concerns such as motherhood, beauty regimes, and domestic upkeep were seen as essential components of a public discussion about expectations of femininity that focused on issues of equal access to the workplace, equal pay for equal work, and an overall attempt to allow women to have control over their lives and their bodies. Theories on how to deal with this hierarchal division of labor were vastly varied. For example, Marxist feminists saw the capitalist economic structure as inherently patriarchal. Thus, attempts at more equal power relations between men and women were reliant upon a restructuring of the economic system. Conversely, more conservative feminists, who constituted the liberal feminist school of thought, looked more closely at ways to reform the current system to allow for more women within the public sphere. These various feminist schools reflect the differences in conceptualization and approach to the concept of gender. Some feminists worked relentlessly to prove that both men and women could be rational, active members of public space, challenging the preconceived notion that masculine gendered characteristics are inherent to men. Others fought to revalorize qualities of femininity, attempting to recognize the power of women’s roles as well as the usefulness of feminine approaches in public space. What united many of the perspectives was a desire to engage in a larger public discussion about issues of masculinity and femininity and how they influence the daily lives of women and men.

GENDER AND ELITISM: WHOSE “PERSONAL IS POLITICAL”?

Since the beginning of the second-wave movement, the meaning of the term gender has been disputed. Despite some public understanding of the second wave’s fight for gender equality for women, the movement was fractured, with discontentment from many sides. For example, although Betty Friedan’s The Feminine Mystique (1963) was commended for its attack on women’s limited role as domestic caretaker, her analysis was criticized for its elitism. Although Friedan called attention to the oppression rooted in gendered expectations and roles, her white, heterosexual, middle-class perspectives were specific to a single group of women. Such criticisms called into question the stability of the category woman. Do all women share a similar experience? Questions of race, class, and sexual orientation brought forth recognition that gender expectations and gender identity were not the same for all women, nor were they the same for all men.

Though cross-cultural comparisons were used to draw attention to the socialization of gender roles and expectations, many second-wave feminists still failed to recognize the cultural differences within their own communities. As gender expectations and what it means to be a woman were debated, critics began to question the assumption that all women shared the same experiences. In her 1981 book Ain’t I a Woman, the literary scholar bell hooks discussed the racism that circulated and continues to circulate in feminist literature. She identified the struggle for black women to find a space of visibility within a movement embedded in racism. Her analysis, and those of other critics, draws attention to both the racial and economic advantage embedded in the positions of many noted feminists of the second wave. Theorizing about “women” when in actuality only discussing the experiences of white women exemplified this privileged perspective. Core issues such as beauty and domestic expectations were far removed from racially oppressed women whose economic and social positions typically demanded out-of-home labor. As hooks pointed out, the racism within the women’s movement coupled with the sexism in the civil rights movement left little to no space for a public debate about the experiences and oppression of black women.
Compounding the criticisms of racial and economic privilege were the objections voiced by members of the lesbian feminist school of thought, who pointed out the homophobia inherent in the women’s movement. The notion of a shared sisterhood of all women provoked anger from those women who felt their experiences differed and their perspectives were silenced. Often, core discussions of gender focused on social expectations of men and women as they function in heterosexual relationships. Lesbian feminists pointed out the institutionalization of heterosexuality and the unwillingness of many heterosexual feminists to challenge this unequal power dynamic.

Overall, there was a sense from critics that discussions of power within the second-wave feminist movement were oversimplified. Many feminists failed to recognize that they could be both oppressed and oppressor, thus ignoring the intersections of race, class, and sexual orientation in a society that privileges white, male, middle- or upper-class status, and heterosexuality.

COMPLICATING AND DESTABILIZING GENDER

As gender became a more common topic of discussion in both academic institutions and activist forums, its unstable and complex nature was a frequent part of debate. Attempting to move past the charges of elitism and oversimplification, scholars such as Joan Scott defended the usefulness of gender as an analytic category. Scott maintained that gender is not constant, but rather constantly shifting and changing as it operates in multiple fields (1986). She argued that discussions and studies utilizing gender as an analytic category must be carefully understood based on context and history. Her analysis defended its usefulness while simultaneously complicating the power dynamics that intersect with gender construction.

Similarly, the gender scholar Judith Butler significantly contributed to the complication of a theoretical understanding of gender. Her Gender Trouble (1990) is foundational in pointing out the intricate connection between gender and sexuality. Butler drew attention to the policing of heterosexuality through gender norms, arguing that a core component of the current gender system, which calls women to be highly feminine and men to be highly masculine, is as much about upholding heterosexuality as it is about policing public space. Additionally, Butler is noted for her theory of gender performativity, which holds that gender is maintained through performative acts that naturalize and create an appearance of an internal essence. Her position can be understood as an extreme social constructionist stand that sees both sexuality and gender as constitutive of our practices, policies, language, and overall daily norms.

Both Scott and Butler echo the reflective position taken by many gender scholars in the last decades of the twentieth century. The desire to complicate gender and illuminate its instability is found in works that addressed the realization that gender cannot be equated with woman. Masculinity studies became much more common, and indeed expected when addressing issues of gender, and gender literature and courses more frequently recognized the gendered nature of every individual. Most gender literature focused on femininity and oppression; however, a look towards masculinity revealed the limiting role placed upon many men who are primarily defined by success in the public realm. Expectations of aggression, detachment, and control are problematic for both men and women. The antisexist male activist Jackson Katz has since 1993 created high school and college-based educational programs, which include videos and lectures that focus on the construction of masculinity in the United States and the violence inherent in many male-gendered norms. The aim is to liberate not only women but also men from limited roles and expectations; recognizing that all individuals are gendered allows for a more complete understanding of how the patriarchal system is maintained. Privy to earlier criticisms, scholars studying masculinity are acutely aware of the vast differences in norms and expectations across racial and class divides.

Many gender scholars have called for an understanding of gender that moves beyond basic binary discussions of masculinity and femininity to a greater understanding of transgendered issues and the fluidity of gendered identities. The twenty-first century has brought more frequent discussions and practices that illustrate at least a partial public understanding of “gender bending.” Public populations are often not familiar with the work of Butler who calls for disruptions of gender expectations. However, cross dressing, transexuality, and overall gendered norm violations are infiltrated in media and other mainstream elements of United States culture. Thus, the public is both exposed and often partially aware of transgendered or gender bending practices. Overall, gender has come to be understood as unstable, allowing for resistance, reinforcement, or recreation of gender identity and expectations in a multitude of ways.

For women who identify with the third wave of feminism, this unstable and complex view of gender is central. Though there still is dispute over whether or not a new wave has indeed emerged, many young women active in gender discussions claim a third wave of feminism whose focus is on creating a solidarity that recognizes difference. In its discussion of difference, coalitions, and popular culture, this third wave, thought to have begun in the mid-1990s, both veered away from and built upon the second-wave movement. Although “third wavers” are as diverse in their positions as the feminists who preceded...
them, there is a general sense that the movement needs to be privy to difference and to build coalitions with other activist movements, because many gendered issues entail struggle against racism, homophobia, class privilege, and imperialism simultaneously. Additionally, although earlier movements criticized popular culture and many of the feminine-gendered expectations, some third wavers distinguish their understanding of gender by claiming power in their sexuality and femininity, seeking ways to co-opt patriarchal ideologies for their own empowerment. This is exemplified in debates over wearing high heels and makeup and embracing one’s feminine sexuality. Some third wavers argue that the pop star Madonna does not represent female oppression, but rather sexual agency. This position strays from the second wave’s desire to free women (typically and critically, mostly white women) from such beauty expectations.

GLOBALIZING GENDER

Twenty-first-century feminism is as diversified as ever, but earlier charges of elitism, both national and international, have produced feminist schools of thought that seek to better understand gendered issues on a global scale. Many postcolonial feminist scholars seek ways to create a feminist solidarity that addresses global concerns while recognizing racial, economic, regional, national, and religious differences. A leader in academic discussions about transnational gender issues is feminist postcolonial theorist Chandra Talpade Mohanty. In Feminism without Borders: Decolonizing Theory, Practicing Solidarity (2003) she provides a summary of her feminist position, which argues for economic stability worldwide for all individuals. Her vision is antiracist and anticapitalist and seeks to create democratic participation through a more complex and reflective solidarity.

Also illustrating a global commitment to gender equity are the many transnational feminist networks such as the Women’s Environment and Development Organization, which “advocates for women’s equality in global policy. It seeks to empower women as decision makers to achieve economic, social, and gender justice, a healthy, peaceful planet, and human rights for all” (2004). This desire to address issues of gender globally comes with a great deal of cultural reflexivity and international collaboration. Global scholars and transnational feminist networks seek to acknowledge and manage issues of difference that arise in multicultural coalitions. Despite these challenges, twenty-first-century gender scholars and activists find it increasingly difficult to ignore globalization and the fact that worldwide gender inequity involves a multiplicity of economic, environmental, ethnic, and many other postcolonial factors.

Although gender research has followed numerous threads, the intellectual compass seems to be pointing toward a focus on global issues. This recent direction is frequently freighted with a complicated theory of power and difference that requires a highly reflective researcher who can represent such issues without colonizing the voices of those they study. Despite shifts in the focus of gender research, the twentieth and twenty-first centuries have proven the importance and longevity of gender as an essential topic of political and social discussion.

GENDER, ALTERNATIVES TO BINARY

It is widely taken for granted, especially in Europe and the Americas, that gender is binary: that male and female are sharply different in feelings, anatomy, and behavior, and
all people ought to fit neatly into one of these two categories. Certain realities contradict this assumption, including homosexual orientation, intersex (hermaphrodite) anatomy, and transvestite behavior, and they can appear in every society. A small number of nonwestern societies accommodate alternative genders, including the hijras of India, the Native American Half-Man—Half-Woman, and the Navajo nadle. From these and other cases, social scientists infer that there can be creative ways for people to be legitimate members of society without necessarily fitting squarely into only-male or only-female categories.

In the case of the hijras, teenage boys in India expect to become husbands and fathers, but a few realize that, because they are homosexual or intersex, they will not fulfill traditional male roles. These ones find that some cities harbor a group called the hijras who adopt female names, dress, and speech, and who relate to each other as sisters, and as daughters to their leaders. Their place in society is based on the belief that, even if homosexuals and intersex males will not marry women or have children, they still possess male procreative energy that they can transfer by blessing bridegrooms at weddings and baby boys at birth. By giving up normative male identity to become hijras, they are thought of as former males who help other males become better men. The hijras also constitute a separate caste, made distinct from other castes by their own rituals, taboos, myths, and patron goddess.

A “true” hijra eventually undergoes an emasculation ritual to remove the male genitalia. Ideally, they earn livings from the blessing rituals, but many have to supplement that income through prostitution. Others marry male lovers. Sex between a man and a hijra is not thought of as homosexual; it is heterosexual in the sense that a hijra is not a man, and not a woman either, but a third gender.

During the nineteenth century, Native American societies expected boys to become warriors, but at puberty a small number displayed a female-oriented vision of one’s future that permitted them to enter into the status of the Half-Man—Half-Woman. Society valued them as mediators because it was thought that they were especially able to see both sides of a question. They also served as chaperones during courtship, and were believed to possess special magical energy that supported blessings and healing. Sometimes a Half-Man—Half-Woman became an additional wife in a polygamous marriage. As with the hijras, a sexual relationship between a man and a Half-Man—Half-Woman was considered to be heterosexual.

The Navajo nadle moved between quasi-male and quasi-female identities. The nadle began life as an intersex, which eliminated options such as becoming a father, hunter, or warrior. But nadles were believed to have a special ability to manage wealth, and it was a blessing to have a nadle in the family. The nadle was more woman than man: She practiced women’s activities such as cooking, had the legal status and sex life of a woman, and was usually (but not always) addressed as a woman. In other circumstances the nadle could be manlike, as in presiding over rituals or managing wealth. The nadle was appreciated as a wise mediator for the same reasons the Half-Man—Half-Woman was.

Some Navajo transvestites, also called nadles, could dress as either male or female, depending on the activity, and could have sex with either men or women. The transvestite had more freedom than the intersex nadle to move between male and female roles. Many other Native American societies had gender statuses that enabled a limited number of people to alternate gender roles, but this flexibility became very rare as Native American life was assimilated into the dominant western culture of the United States. The same kind of cultural assimilation also brought an end to other societies’ gender alternatives, including the Thai kathoey and the Philippine bakla.

Alternative gender models are not whimsical lifestyle options. The pressures that steer people into these roles are approximately as powerful as those that require other people in the same societies to conform to male or female models. In most cases, the people who enter these statuses remain in them for the rest of their lives. Very few people in these societies have these statuses, partly because very few are inclined toward them, and partly because these societies have ways to discourage large-scale deviations from normative binary gender.

The alternative models challenge the assumption that binary gender is inevitable. The anatomy of male, female, and intersex can be universal, but gender—the cultural interpretation of sexuality—is highly variable. Yet it is difficult to use an alternative model as a formula for changing the ways westerners experience gender, because each alternative form is intimately situated within a matrix of local beliefs, statuses, and values, and they are not easily adapted from one society to another. Another reason is because reform in the western world is concerned with legal rights. Following in the footsteps of feminist reform, it identifies a portfolio of well-established rights that heterosexuals have (to marry, for example, or to raise children) and then extends those rights to gays, lesbians, bisexuals, intersexes, and transgendered people. This is not an experiment in creating new categories, but rather universal access to existing rights. For those two reasons, nonwestern alternatives to binary gender are unlikely to lead to western versions of hijras or nadles.

Still, one cannot ignore certain provocative questions that arise in light of these alternative models. If western societies become more tolerant of gay and lesbian people,
along with practices such as same-sex unions, how will gay or lesbian roles coexist with binary gender roles? If some gay men are normatively male in everything except their sex lives, are they not ironically reinforcing the tenets of binary gender, even as conservatives accuse them of subverting it? Aren’t female impersonators such as Danny LaRue, Holly Woodlawn, The Lady Chablis and RuPaul reinforcing binary gender by distilling an essence of feminine looks and personalities?

Fiction presents some imaginative insights. Ursula LeGuin’s science-fiction novel *The Left Hand of Darkness* (1969) describes a planet where humans are “hermaphroditic neuters” who periodically morph into male or female forms to mate with the opposite form. Each can become male or female, father or mother, then revert back to neutral anatomy. Earthlings are considered perverts because they are stabilized in male or female form, which is taken to mean that they are always sexually aroused. Jeffrey Eugenides’s *Middlesex* (2002) is the story of a teenage girl who abruptly learns that she is genetically male, and that puberty has been changing her body from girl to man. At the point in the story where this girl/man becomes a medical curiosity, there is a twenty-seven-page presentation on the anatomy and psychology of the intersex condition, as well as facetious accounts of gender-socialization theories and sociobiology as a backlash against them: “Men and women, tired of being the same, want to be different again” (p. 478).

Alternatives to binary gender reveal that there is much more to gender than just sexuality, and that there is more than one way for a society to understand gender. In the words of Cal, the girl who develops into a man in *Middlesex*, “My family found that, contrary to popular opinion, gender was not all that important” (p. 250).

**GENDER AND DEVELOPMENT**

Gender and development is an interdisciplinary field focusing on the social relations between women and men in developing and transitional economies. The field has grown rapidly since the 1970s and includes “innovations in research, analysis, and political strategies brought about by diversely located researchers and activists,” as well as a set of practices and discourses that are institutionalized within multilateral organizations (such as United Nations agencies and the World Bank) and national governments (Cornwall et al. 2004, p. 2). Many fine collections have been compiled on gender and development (see Cornwall et al. 2007; Jacquette and Summerfield 2006; Benería and Bisnath 2001; Jackson and Pearson 1998; and Visvanathan et al. 1997). There are also several excellent summaries tracing the intellectual and political evolution of this field from the 1970s to the 1990s (see Elson 1999; Bakker 1999).

This entry will concentrate on gender issues in the context of development theories and policies since the late 1990s, focusing on five related but distinct issues that are debated in the literature: gender and poverty, women’s empowerment, paid employment and unpaid work, gender and the macroeconomic policy environment, and institutional issues and gender mainstreaming. For the large and growing literature on other topics in gender and development, see: Mark Pitt and Shahidur Khandker (1998), Linda Mayoux (1999), and Naila Kabeer (2001a) on microfinance; UNESCO (2004) and Michael Kevane (2004) on education; Harriet Presser and Gita Sen (2000) on population; Gita Sen, Asha George, and Piroska Ostlin (2002) on health; UNFPA (2005) on the feminization of AIDS; and Claudia Garcia-Moreno et al. (2005) and Sunita Kishor and Kiersten Johnson (2004) on violence against women.

**DEFINING GENDER AND DEVELOPMENT**

The literature on gender and development originated in opposition to views common in the 1970s and 1980s that women were excluded from the development process and needed to be incorporated into mainstream policies, institutions, and programs. Early gender and development theorists critiqued the prevailing development paradigm.
that promoted market-led development and structural adjustment and stabilization packages as a response to debt and balance-of-payments problems, as well as the view that women should be integrated into a process that benefits a few and impoverishes many (Benería and Sen 1982). In contrast to the earlier “women in development” literature, gender and development theorists had an explicit objective of social transformation, both of the ultimate aims and practices of development and of the relations between men and women (Jackson and Pearson 1998).

The feminist academics and activists who chose the language of gender used it in a particular way. Gender is a social construct that refers to the relations between women and men and reflects hierarchies among them, based not only on their biology, but also on their age, life-cycle position, ethnicity, race, income and wealth, and other features (Barker 1999). Gender relations change over time and vary across societies, but in all societies, they structure the division of labor and distribution of work, income, wealth, education, productive inputs, publicly provided goods, and the like.

Kate Young (1997) outlines six issues that characterize approaches used by gender and development scholars. (1) The focus is not on women per se but on gender relations, that is, relations between women and men in a variety of settings interlocked with other social relationships such as income, race, caste, and ethnicity. (2) Women are viewed as active agents, although they may not have perfect knowledge or understanding of the roots of discrimination and subordination. (3) The perspective is holistic, and focuses on the reproductive aspects of social and economic life (caring for dependents), as well as the gendered social relations of production and distribution of goods and services. (4) Development is viewed as a set of complex processes involving economic, political, and cultural transformation over time and space that should aim to produce improvements in capabilities, freedoms, and living standards for individuals and societies. (5) Achieving gender equality and women’s empowerment requires multiple approaches and strategies that will necessarily differ by circumstances. (6) The role of organization and collective action by women is central to the achievement of gender equality and women’s empowerment.

THE DEVELOPMENT CONTEXT: 1990–2007
Examining the field of gender and development since the 1990s requires an understanding of the global political economy at the turn of the century. Although globalization had accelerated, the patterns were uneven (Stiglitz 2002). Some countries, such as China and India, were growing rapidly while others, such as Ecuador and Bolivia, were growing only slowly. Many countries, especially those in sub-Saharan Africa, were experiencing negative growth (Birdsall 2006; Wade 2004). Although there is debate over whether global poverty has increased or decreased since the 1990s, analysts agree that a billion-plus people were living on less than $1 per day in 2000 (Reddy and Minoiu 2006; Chen and Ravallion 2004; UN Millennium Project 2005). The widening of income inequality both within and between countries, a series of environmental crises from loss of species to global warming, growing religious fundamentalism, and violence and conflict also posed major development challenges (Milanovic 2006 and 2005; Melnick et al. 2005).

The concern over poverty, inequality, and differential economic growth led world leaders from 189 countries in 2000 to adopt the Millennium Development Goals (MDGs), a set of eight goals with related time-bound targets to reduce extreme poverty and its correlates by 2015 (UN Millennium Project 2005; Thorbecke and Nissnake 2006). The MDGs have become the global development policy paradigm for the early part of the twenty-first century and one of the key entry points for advocates of gender and development. Although many development economists and activists agree on the importance of reducing absolute poverty and improving human capabilities, they disagree about whether the MDGs can be achieved in the current era of globalization, and whether growth can be made to be pro-poor.

GENDER AND POVERTY
Reducing gender inequality and empowering women is the third Millennium Development Goal. In setting this goal, governments recognized the contributions that women make to economic development and the costs to societies of the multiple disadvantages that women face in nearly every country (Grown et al. 2005). As noted in the World Bank’s Engendering Development:

In no region of the developing world are women equal to men in legal, social, and economic rights. Gender gaps are widespread in access to and control of resources, in economic opportunities, in power, and political voice. Women and girls bear the largest and most direct costs of these inequalities—but the costs cut more broadly across society, ultimately harming everyone. For these reasons, gender equality is a core development issue—a development objective in its own right. (World Bank 2001, p. 1)

Beginning in the 1990s, the concept of poverty broadened beyond a focus on shortfalls in income or consumption to lack of capabilities (e.g., education and health), lack of voice, lack of opportunities, and lack of dignity. When these broader criteria are factored in, females appear to be more vulnerable than males to the
risk of poverty and vulnerability, although data limitations make it difficult to quantify the relative proportion of female poverty (Quisumbing et al. 2001). They also experience poverty differently than men (Razavi 1999; Jackson 1998). Because of their responsibilities for social reproduction, as well as gender inequalities in ownership of assets and access to employment and productive resources, women find it harder than men to transform their capabilities into steady income streams that would allow them to escape poverty (Deere and Doss 2006; Cagatay 1998).

Early work on gender and poverty focused on female-headed households, identifying them as the poorest of the poor (Chant 2003, p. 11). In a meta-analysis of sixty-one empirical studies, Mayra Buvinic and Geeta Rao Gupta (1997) found that in thirty-eight studies, female-headed households were overrepresented among the poor. More recent work has debunked the notion equating female headship and poverty, noting the wide economic diversity of female-headed households in countries around the world and the heterogeneity of intrahousehold sharing rules, which may disadvantage females in male-headed households more than females in female-headed households (Chant 2003).

Since poverty encompasses many dimensions other than earned income, including lack of public provision of goods and services, access to common property resources, and voice in political processes and decision-making, poverty reduction strategies need to be multidimensional. Within the context of the MDGs, Caren Grown and colleagues (2005) recommend seven strategic priorities to achieve gender equality in the context of poverty reduction, including strengthening opportunities for postprimary education for girls, guaranteeing sexual and reproductive health and rights, investing in infrastructure to reduce women’s and girls’ time burdens, securing women’s and girls’ property and inheritance rights, eliminating gender inequality in employment by decreasing women’s reliance on informal employment and closing gender gaps in earnings, and significantly reducing violence against girls and women.

Although the broader focus on the gender dimensions of poverty is welcome, Cecile Jackson (1998) cautions against seeing gender and development as a variant of poverty problems; poverty is not entirely responsible for the subordination of women, and even antipoverty strategies may not be sufficient on their own to improve the position of women.

**WOMEN’S EMPOWERMENT**

The concept of women’s empowerment features prominently in the gender and development literature, and many development interventions not only aim to increase income and assets but also to empower women. The World Bank’s sourcebook on *Empowerment and Poverty Reduction* (Narayan 2002) defines *empowerment* as the expansion of freedom of choice and action. Feminist scholars point out that women’s empowerment encompasses unique additional elements. Women are not just one group among several disempowered subsets of society, but are spread throughout all categories of disadvantage, including race, caste, ethnicity, and class. Second, the household and interfamilial relations are a central locus of women’s disempowerment in a way that is not true for other disadvantaged groups (Malhotra et al. 2002). At the same time, empowerment requires systemic transformation in household relations, social norms, and market and government institutions (Kabeer 2001b).

**PAID EMPLOYMENT AND UNPAID WORK**

Access to employment and income are a critical component of poverty reduction and women’s empowerment. Women’s participation in paid employment has increased everywhere since 1990, but there is still a large gap between female-male activity rates in most regions. Most analysts attribute the increase to opportunities provided by globalization and structural changes, including commercialization of agriculture, industrialization, and the replacement of unpaid provision of services by women in families and communities by the paid provision of services by women employed in both the public sector and private firms (Standing 1999). Controlling for long-term economic development, Cagatay and Özler (1995) find that structural adjustment policies and export-oriented growth lead to a feminization of the labor force.

As the International Labor Organization (ILO 2007) points out, indicators of paid employment (such as labor force participation rates or the female share of paid nonagricultural employment) show little about the likelihood of being employed or having decent work. In almost all regions, the female unemployment rate is higher than the male rate, occupations are sex-segregated, and gender gaps persist in earnings. Women predominate in informal employment—jobs that lack formal contracts, security, benefits, or social protection (ILO 2002). The average earnings from informal employment are too low; in the absence of other sources of income or social protection policies, to raise households out of poverty (Chen et al. 2005). And the conditions of informal employment perpetuate the financial dependency of women wage earners on male relatives and partners because they do not earn enough in informal employment to support themselves and any children they may have (Chen et al. 2006).

Time-use data are necessary for calculating the total amount of work, paid and unpaid, that women and men perform. Although progress has been made in collecting

---

*Gender and Development*
time-use statistics, data are limited and trend data are lacking (UNDESA 2006). Yet available evidence suggests that women and girls spend more time on unpaid work than men and boys, and when both paid and unpaid work is taken into account, women and girls have a longer working day than men and boys. Jacques Charmes (2006), for instance, finds that females in Benin spent 7.5 hours a day in paid employment compared to 5 hours a day for men in 1998, yet females spent almost 3.5 hours per day on unpaid work, while men spent just over 1 hour. Moreover, a number of studies suggest that women’s performance of overlapping activities has intensified with globalization (Floro 1995).

GENDER, MACROECONOMIC POLICIES, AND THE ENABLING ENVIRONMENT FOR POLICY REDUCTION

The development economics literature is divided about the policies that promote growth that is pro-poor, with some arguing for greater liberalization of trade and financial capital markets and others arguing for greater control over markets and attention to policies that create domestic demand for goods and services. Most of the gender and development literature takes a skeptical position toward the view that gender equality can be achieved in a context of export-led growth (Benería 2003; Elson 2002).

In this vein, Stephanie Seguino and Caren Grown (2006) propose shifting economies from profit-led, export-oriented growth to wage-led, full-employment growth. This entails state-level industrial and agricultural development strategies to promote both articulation with the domestic economy and an export product mix that permits rising female wages without a (large) negative effect on exports, as well as policies that stabilize the economy, including limits on physical capital mobility (inward and outward foreign direct investment) and capital controls that act as speed bumps, reducing financial volatility. Elissa Braunstein (2006) notes a number of other policies specifically targeted to foreign direct investment and gender equity simultaneously, including restrictions on entry of foreign direct investment in key strategic industries, support to domestically owned firms for technological and human capital upgrading with priority for women workers, and the enforcement of core labor standards.

DEVELOPMENT INSTITUTIONS AND GENDER MAINSTREAMING

The goal of gender and development—gender equality and women’s empowerment—is now institutionalized in policy and organizational mandates. At the Fourth World Conference on Women in 1995, the international community endorsed gender mainstreaming as a key institutional response for promoting gender equality and empowering women. In 1997 the UN Economic and Social Council defined gender mainstreaming as:

the process of assessing the implications for women and men of any planned action, including legislation, policies or programs, in all areas and at all levels. It is a strategy for making women’s as well as men’s concerns and experiences an integral dimension of the design, implementation, monitoring and evaluation of policies and programs in all political, economic and societal spheres so that women and men benefit equally and inequality is not perpetuated. The ultimate goal is to achieve gender equality. (UN ECOSOC 1997)

This definition makes clear that gender mainstreaming is a means toward the achievement of gender equality and women’s empowerment. It is both a technical and political process requiring shifts in organizational culture and ways of thinking and in the structures and resource allocations of organizations (Oxaal and Baden 1997). As currently understood, gender mainstreaming encompasses all aspects of planning, implementing, and monitoring any social, political, or economic action.

Feminist scholars have pointed out a number of problems with the way that gender mainstreaming has been operationalized in development institutions. Some claim that “doing gender” has reduced a fundamentally political process aimed at social transformation into a technical process reliant on tools, checklists, and training (Mukhopadhyay 2004). Other critiques focus on the gap between governmental policy commitments and actual implementation (Verloo 2001). Within multilateral and bilateral development organizations, the process of gender mainstreaming has stopped short of operations—of the very dimension that impacts development on the ground and can show results in terms of development effectiveness (Hannan 2004; Moser and Moser 2005).

Others point out that gender mainstreaming has not been pursued fully or systematically enough to support definitive conclusions about its success or failure (Woodford-Berger 2004). In most cases, the process is incomplete or not properly implemented. Since it is likely that mainstreaming will continue to be the dominant strategy for incorporating gender equality issues in development policy institutions, more work will be necessary to understand the conditions under which it can successfully achieve its objectives.

CONCLUSION

There are many development challenges to be tackled in the early decades of the twenty-first century. The field of gender and development has much to offer for developing both new analytic paradigms and new institutional practices.

Gender Gap

Gender gap refers to systematic differences in the outcome of men and women on a variety of issues ranging from economic participation and opportunity, political empowerment, and educational attainment to health and well-being. Unlike sex stereotypes that ascribe social roles to men and women based on a traditional distribution of labor within a particular society and thereby reinforce stereotypes, gender gap measures difference in the outcome to gain a better understanding of how these differences can be narrowed. Closing the gender gap is constitutive of

GENDER EMPOWERMENT MEASURE

SEE Women and Politics.
achieving gender equality, which can be defined as “a stage of human social development at which the rights, responsibilities and opportunities of individuals will not be determined by the fact of being born male or female, in other words, a stage where both men and women realize their full potential” (Lopez-Claros and Zahidi 2005, p. 1).

State policies are an important factor in shaping gender relations and, in certain respects, state actions are constitutive of gender. Countries vary significantly in their efforts to close the gender gap through “women-friendly” policies—social policies that seek to mediate social inequalities, particularly those flowing from women’s disproportionate responsibilities in caregiving. A 2006 study by the World Economic Forum (WEF) examined fifty-eight countries and their efforts in closing the gender gap. The Nordic countries, particularly Sweden, Norway, and Iceland, had the lowest gender gap. These states are characterized by liberal societies, protection of minorities, and a comprehensive welfare state that actively promotes gender equality through women-friendly policies. The United States was ranked seventeenth. The United States ranks poorly on the specific dimensions of economic opportunity and health and well-being, compromised by meager maternity leave, the lack of maternity leave benefits, and limited government-provided childcare. The overall rating is low, given that many scholars and policymakers consider the antidiscrimination and sexual violence legislation in the United States to be the strongest in the world.

Countries with the largest gender gap were four of the seven predominantly Muslim countries, namely Jordan, Pakistan, Egypt, and Turkey. Sweden, in spite of being the country with the lowest gender gap, encounters occupational segregation with women working predominantly in the public sector. Thus no country has yet achieved full gender equality, making gender gap a global phenomenon.

Since 1990 the United Nations Development Program (UNDP) has published an annual report that examines human development based on four indices: the Human Development Index (HDI), the Gender-Related Development Index (GDI), the Gender-Empowerment Measure (GEM), and the Human Poverty Index (HPI). Based on these indices 174 countries are ranked. For the evaluation of gender gaps the GDI and the GEM are important measures. The GDI is composed of an average of three indices that measure gender differences in terms of life expectancy at birth, gross enrollment and literacy rates, and earned income. The GEM is an average of three other variables that reflect the importance of women in society, specifically the participation of women in employment, the male to female ratio among administration, managers and professional and technical workers, and the female to male Gross Domestic Product (GDP) per capita ratio calculated from female and male share of earned income. While the GDI assesses the status of women in society the GEM points to the relative empowerment of women and men in the political and economic spheres.

Based on the GDI and GEM countries are ranked annually, thereby making it possible to evaluate their progress in closing gender gaps as well as the relative status of countries vis-à-vis each other on gender equality. While the indices are important tools for measuring the results of gender discrimination they do not address the underlying causes. Thus, although indices represent an important first step in comparing and monitoring the progress of countries toward closing the gender gap they are not sufficient to actually reduce gender discrimination. To promote policy change these indices need to be accompanied by, for instance, broader strategies for change that address the underlying causes of gender discrimination and best practice examples that enable governments and activists to learn from each other about how to close gender gaps.

GENDER GAPS IN ECONOMY, POLITICS, EDUCATION, AND HEALTH

Economic participation, or a high employment rate of both men and women, is important for lowering household poverty, enabling women to establish and maintain an independent household, and supporting an inclusive society. Access to employment alone is not sufficient to achieve gender equality. Equality within employment requires a closing of the gender pay gap, meaning that women are paid the same as men for the same work or work of equivalent value, and establishing economic opportunities to reduce horizontal and vertical segregation. Horizontal segregation means women and men are concentrated in different sectors and professions, with women working in areas with less opportunity for professional development and low pay. States can promote the opening of a wider range of occupations to women through equal opportunity legislation and affirmative action programs as well as antidiscrimination and sexual harassment legislation. Vertical segregation refers to the blocking of higher positions for women or limited opportunities for women to advance to managerial professions (the proverbial “glass ceiling”). To promote women’s upward mobility the state can establish, for instance, social services that provide caregiving for dependents, limit working time, and promote a “work-life balance.” (International Labor Organization 2003.)

Political empowerment of women is concerned with equitable representation of women in decision-making structures and their ability to influence the policymaking process. While most countries have de jure equality in political participation, actual participation varies by country. A 2005 United Nations report found that “women
still hold only 16 per cent of parliamentary seats worldwide (only Rwanda and the Nordic countries have come close to parity) … by the end of 2004, 81 countries had adopted some form of affirmative action, such as party quotas or reserving seats for women in parliament to ensure their political participation” (United Nations 2005, p. 16).

Education has gender gaps in a number of areas, such as literacy rates and years of schooling (primary, secondary, and tertiary education). While the gender gap in primary and secondary school attendance has narrowed over the past thirty years, the gap is still wide in tertiary education, particularly computer science and mathematics.

Finally, gender gaps can be found in health and well-being. The focus is particularly on access to nutrition, health care, reproductive facilities, and overall security in terms of safety and integrity of a person. A 2005 OECD study pointed to the relationship between birth rates and attitudes toward equality. Countries with “more traditional family structures in modern economies face chronically low birth rates, whereas the birth rate trend is positive and the demographic structure more balanced in countries where gender equality in the workplace is more developed. For these countries, that points to fewer problems with ageing, as well as higher labour activity and a more robust economy” (Mörtvik and Spånt 2005).

Gender gap and gender equality are two sides of the same coin. In order to achieve gender equality gender gaps have to be closed. Looking at gender gaps and monitoring their development can serve as a valuable tool for policymakers and activists to integrate gender equality in economic models for sustainable growth and development and create conditions for inclusive societies.

GENDER STUDIES

Interdisciplinary gender studies started with the opening call of the new feminist or women’s liberation movement in the United States—Betty Friedan’s 1963 The Feminine Mystique, the sociological critique of Freud’s view of women’s natural inferiority.

This movement inspired research, mainly sociological and anthropological but also economical, historical, and psychological. During its first two decades the terms sex roles and sexual stratification were current, until the terms gender, gender roles, and gender relations gained circulation and replaced them. This research shared a conviction and a goal. The conviction is that equal status of women and men is possible today, all the forms and causes of women’s inferior status in different societies and in different historical periods notwithstanding. The goal of this research is openly declared: to discover the ways and means to facilitate the achievement of gender equality.

The basic questions/problems/analyses of gender research are the following:

The formal political equality achieved by the old, “classical” women’s movement did not result in de facto equal opportunity and participation of women. Why?

The status of American (and other Western) women declined after World War II. Why?

Marx and Engels postulated inevitable stages of development from primitive communism with no private property, no family, and no gender inequality, through stages of different class societies toward socialist revolution leading to communism, where private property (the means of production), the nuclear family, and gender inequality will all disappear. They were in error. Where did they go wrong?
Gender Studies

Were/are there any societies where women are equal? What were/are their characteristics? What is the relative importance of economic conditions and religious beliefs for the status of women?

What is the actual and possible impact of recent innovations on the likelihood of achieving equality for women? In particular, research centers on improved means for birth control, on the electronic and computer revolutions in the economy, and, more generally, on the decline in the importance of physical strength for most kinds of work that traditionally gave men an advantage in occupational work.

Can there be solidarity between women of different social classes and “races”? In particular, researchers differed on the possibility of cooperation between white, educated “middle-class” women and “women of color” belonging to the “working classes.”

How serious is the “sex-typing” of occupations? How unequal is the distribution of men and women over the range of occupations and their position in the hierarchies of economic and academic organizations, public service, and the professions? How does the income of employed or self-employed women compare to that of men?

How do the attitudes to work of women and men compare? In particular, research centered on the so-called instrumental attitude toward work as compared to interest in its content and quality, as well as interest in advancement at work.

What are the characteristics and the impact of “genderized” education of boys and girls in families, schools, and religious organizations compared to the impact of their own life experiences?

Does the fact that most babies are nurtured by their mothers during the first year of their life necessarily cause a stronger tendency toward and capacity for attachment in females and a stronger tendency toward and capacity for autonomy in males?

What are the achievements and chances of achieving reforms and real changes in the current inferior status of women and their segregation, preached and maintained by leaders of various religious communities?

Has there been a qualitative impact from the entry of women into local, national, and international politics and into councils, parliaments, governments, the diplomatic corps, the army, the judiciary, and law enforcement?

What was the impact of women’s massive entry into the labor market and their demand for equality on the incidence, age, and frequency of marriage and divorce and on the birth rate? How has family law changed? What importance has the availability or absence of civil marriage and divorce and of the recognition of cohabitation (as well as the recognition of same-sex unions) for the status of women?

What custody policies have been tried, and how can their degree of fairness—to mothers as well as to fathers and children—be assessed? How can the degree of practicality of solutions of “shared custody” be assessed? The same goes for policies encouraging equal parenting and their effectiveness as well as for the quantity and quality of men’s participation in child care and housework.

What have we learned about fighting violence against women, about the effectiveness of safe houses for battered women, and about police action against violent husbands and other partners and their reeducation? What is the experience of public action against clan murder of women in the name of “family honor”? What is the experience of public action against “bride-price murders”? What success have we had in eliminating the mutilation of girls (“female circumcision”)? How successful is the fight against rape? The same goes for the fight against the sexual abuse of children—especially girls.

Does pornography encourage sexual violence and should it be banned, or does it relieve violent sexual urges? Is prostitution mainly “sex work” or “sexual slavery”?

Should women establish separate organizations (such as trade unions or political parties) and institutions (such as health services, banks, or “women’s studies” university departments) to gain appropriate services and attention? What are the achievements and defects of such separate organizations and institutions?

What is the impact, actual and potential, of women’s international nongovernmental organizations on the United Nations and through them on pressuring the member states to raise their standards of women’s participation in politics and the economy?

Since the 1990s some “postmodernist” or “postfeminist” literature discourages the struggle for global gender equality. The writers deny the possibility of a common rationality of women and men, as well as that of common interests and even of a common rationality of different groups of women—those who belong to different classes and races, to Western or Eastern societies, as well as of women with different sexual orientations. They rule out the possibility of gender studies advancing knowledge of the causes and circumstances of and the possible remedies to the ubiquitous sociopolitical problem of gender inequality. Fortunately, the ongoing gender studies are too robust and successful to be obliterated by this unserious trend. The results of these studies, moderate as they may be, are very encouraging.

General Agreement on Tariffs and Trade

The General Agreement on Tariffs and Trade (GATT) is the predecessor to the World Trade Organization (WTO). From 1947 to 1994, the GATT provided the world’s main institutional framework for multilateral trade negotiations. It was created in Geneva in 1947 to remedy the protectionism and economic discrimination that arose during the interwar period and that arguably deepened the Great Depression. It was thus designed to facilitate nondiscriminatory trade liberalization among the world’s major trading partners.

GATT members reduce trade barriers through periodic negotiating rounds, each of which produces an agreement that must be ratified by all members before it takes effect. Although these negotiations typically take place in small groups, the resulting concessions are extended to all members through the most-favored-nation rule, which grants each member the same treatment as the most-favored trading partner. The most-favored-nation rule ensures that any liberalization achieved during GATT rounds is nondiscriminatory. Eight rounds have been concluded as of 2006: Geneva (1947), Annecy (1949), Torquay (1951), Geneva (1956), Dillon (1960–1961), Kennedy (1964–1967), Tokyo (1973–1979), and Uruguay (1986–1994). A ninth, Doha, began in 2001. These rounds have reduced global tariffs on manufactured goods from nearly 40 percent in 1947 to under 4 percent in 2006. These tariff reductions are considered one of the foremost achievements of the GATT system.

Since its founding, the GATT has evolved in important ways. First, its membership has grown from twenty-three countries in 1947 to 149 in 2006. The GATT system has thus become global in scope. Second, the range of policies covered by GATT strictures has expanded over time. While early rounds focused on tariffs, later ones addressed nontariff barriers such as subsidies, voluntary export restraints, and antidumping duties. The Uruguay Round went further still, tackling policies such as technical barriers to trade, sanitary and phytosanitary standards, trade-related intellectual property rights, and trade-related investment measures. Third, the range of economic sectors covered by GATT rules has also grown over time. Whereas early GATT rounds focused on manufactures, the Uruguay Round produced agreements to liberalize trade in traditionally protected sectors such as agriculture, textiles and clothing, and services. Fourth, in 1995 the GATT was subsumed into the newly created WTO. The GATT continues to govern trade in goods but is now part of the broader WTO framework that also addresses new issues such as trade in services and the enforcement of intellectual property rights. Finally, the Uruguay Round also strengthened GATT dispute-settlement procedures, establishing stricter timetables for settling disputes and making it more difficult for losing parties to block unfavorable rulings from dispute-settlement panels. Notably, however, the Uruguay Round did not create any new enforcement mechanisms: Although panels can authorize retaliatory sanctions from complainant states, panels have

**GENERAL AGREEMENT ON TARIFFS AND TRADE**

The General Agreement on Tariffs and Trade (GATT) is the predecessor to the World Trade Organization (WTO). From 1947 to 1994, the GATT provided the world’s main institutional framework for multilateral trade negotiations. It was created in Geneva in 1947 to remedy the protectionism and economic discrimination that arose during the interwar period and that arguably deepened the Great Depression. It was thus designed to facilitate nondiscriminatory trade liberalization among the world’s major trading partners.

GATT members reduce trade barriers through periodic negotiating rounds, each of which produces an agreement that must be ratified by all members before it takes effect. Although these negotiations typically take place in small groups, the resulting concessions are extended to all members through the most-favored-nation rule, which grants each member the same treatment as the most-favored trading partner. The most-favored-nation rule ensures that any liberalization achieved during GATT rounds is nondiscriminatory. Eight rounds have been concluded as of 2006: Geneva (1947), Annecy (1949), Torquay (1951), Geneva (1956), Dillon (1960–1961), Kennedy (1964–1967), Tokyo (1973–1979), and Uruguay (1986–1994). A ninth, Doha, began in 2001. These rounds have reduced global tariffs on manufactured goods from nearly 40 percent in 1947 to under 4 percent in 2006. These tariff reductions are considered one of the foremost achievements of the GATT system.

Since its founding, the GATT has evolved in important ways. First, its membership has grown from twenty-three countries in 1947 to 149 in 2006. The GATT system has thus become global in scope. Second, the range of policies covered by GATT strictures has expanded over time. While early rounds focused on tariffs, later ones addressed nontariff barriers such as subsidies, voluntary export restraints, and antidumping duties. The Uruguay Round went further still, tackling policies such as technical barriers to trade, sanitary and phytosanitary standards, trade-related intellectual property rights, and trade-related investment measures. Third, the range of economic sectors covered by GATT rules has also grown over time. Whereas early GATT rounds focused on manufactures, the Uruguay Round produced agreements to liberalize trade in traditionally protected sectors such as agriculture, textiles and clothing, and services. Fourth, in 1995 the GATT was subsumed into the newly created WTO. The GATT continues to govern trade in goods but is now part of the broader WTO framework that also addresses new issues such as trade in services and the enforcement of intellectual property rights. Finally, the Uruguay Round also strengthened GATT dispute-settlement procedures, establishing stricter timetables for settling disputes and making it more difficult for losing parties to block unfavorable rulings from dispute-settlement panels. Notably, however, the Uruguay Round did not create any new enforcement mechanisms: Although panels can authorize retaliatory sanctions from complainant states, panels have
no power to enforce their own decisions. WTO panel decisions, like GATT decisions, must thus be enforced by trade sanctions from member states.

The GATT system has both supporters and critics. Its supporters contend that it is crucial to achieving the benefits of free trade, such as lower prices for consumers and export opportunities for producers. Supporters also note that GATT rules against trade discrimination make it more difficult for governments to use trade preferences and sanctions as diplomatic tools. Critics, however, claim that the GATT system is deficient in several ways. Some critics, particularly from developing countries, feel that the GATT has not gone far enough in liberalizing trade in agriculture and textiles. Others feel that the GATT has gone too far in constraining national policymaking autonomy. For example, WTO panels have ruled against the European Union’s ban on hormone-treated beef, stating that scientific evidence does not justify such a ban. Critics contend that such decisions about health, safety, and the environment should be left to national governments. Similarly, some have criticized the WTO’s rules on intellectual property rights, which could prevent developing countries from obtaining cheap, generic pharmaceuticals. Finally, some contend that the GATT process is undemocratic because agreements are negotiated by unelected officials.

In light of this controversy, it is worth noting that the GATT is not a supranational policymaking body but rather an institutional forum within which governments negotiate agreements via a consensus decision-making process. Hence, while GATT agreements do constrain policies, no member is constrained without its consent. Moreover, because GATT agreements must be ratified by national governments, the GATT process remains under the control of elected representatives. The GATT is thus not qualitatively different from many other international agreements, all of which constrain national policies. For this reason, the controversy surrounding the GATT probably has less to do with procedural concerns than with disagreements about the substantive content of GATT rules. Finally, it is worth noting that empirical studies have found little evidence that the GATT affects either trade or trade policies. Such research suggests that both supporters and critics of the GATT may have overstated its true importance.

**GENERAL ELECTRIC**

General Electric is one of the largest corporations in the United States. Formed in 1892 from the merger of two U.S. electrical manufacturing companies, Edison General Electric Company and Thomson-Houston Electric Company, by 2006 General Electric had become a $163 billion corporation. General Electric today is a multinational diversified company operating in more than 100 countries in sectors as diverse as aviation and nuclear power, industrial and domestic electrical appliances, personal and industrial finance, and media and entertainment. Despite the level of diversification, its traditional electrical manufacturing activities linked to aviation and energy contributed almost 30 percent of sales in 2006 (General Electric 2006). General Electric continues to be one of the world’s largest producers of jet engines, supplying Boeing and Lockheed Martin, among others.

General Electric’s rise to dominance derived from the company’s ability to restrict market competition through cartelization in the newly expanding consumer markets of the Second Industrial Revolution, and its ability to gain access to large, secure government markets, especially those linked to electricity generation and military equipment. General Electric was at the forefront of the development of international cartels before World War II, instigating market sharing and price-fixing through the creation of “rings” regulated by the International Electrical Association (Barjot 1995). Despite challenges by U.S. antitrust authorities after World War II, international cooperation and market sharing continued (Mirow and Maurer 1982). In the area of military technology, General Electric developed extensive capabilities as a result of high U.S. government defense expenditure during the cold war, and it continues to benefit from the rises in defense expenditure by every government since Ronald Reagan’s; in 2005 its defense contracts amounted to $2.2 billion.

Large protected markets provided the backdrop for diversification into the financial and media sectors. Thus, in the areas of media and entertainment General Electric succeeded in creating large organizations capable of developing market power in entertainment and communication sectors, most notably in 2004 with the creation of NBC Universal, which combined NBC and Vivendi Universal to create a $43 billion media empire (CorpWatch 2006).
General Electric, along with other U.S. manufacturing multinationals, has utilized outsourcing and the establishment of maquila production systems along the U.S.–Mexican border as a mechanism for cost reduction. The company’s diversification into distribution and logistics through its Trailer Fleet Services division has been used to service U.S. companies in the linking of the maquila production centers to U.S. markets. The resultant low-wage and poor labor conditions within the maquila system of production and redundancies and reductions in living standards for U.S. workers has led to extensive criticism of the company from labor unions.

GENERAL EQUILIBRIUM

General equilibrium theory deals with the existence of efficient competitive prices in an individual private enterprise economy. This discussion of general equilibrium theory (GET) is divided into four parts: (1) the context and history of GET, (2) comments on the appropriate mathematization and method of proof, (3) the problems with the parsimonious modeling and solution concept used, and (4) what lies beyond the theory.

CONTEXT AND HISTORY

The French economist Léon Walras (1834–1910) was the first to attempt a mathematization of the conditions necessary and sufficient to determine the prices of all goods and services produced and consumed by firms and individuals in a closed economy. He distinguished between services and durable production goods, and he developed the theory of competitive exchange, noting the possibility of multiple solutions to the existence of competitive prices. In particular he did not prove rigorously the existence of an efficient price system, but he did recognize that this would require the simultaneous solution to the set of equations he had utilized to describe the overall system of production and consumption. In writing down his production conditions, he utilized simple fixed coefficients for the structure of production.

Walras sketched the roles of both a rate of interest and a currency in his system, but these were not fully developed. These features, unlike his integration of production and consumption into a consistent whole, may be regarded as more or less undeveloped when compared with the market structure for the production and consumptions of goods and services. Although Walras discussed the important role of government, he left it out as being beyond the more strictly economic problems he was addressing.

The full modeling of an exchange and production economy presented a challenge. The construction of a formal closed mathematical model of the economy called for Draconian simplification, and it was thus a major achievement in abstraction. As is often the case, even in the purest of mathematical economics, the distinction between the verbal treatment and the mathematization offered is often considerable. Words permit a richness of discourse at the cost of precision, while mathematics offers precision and logical tightness at the cost of qualification, nuance, and the recognition of complexity. Mathematics thus facilitates the analysis at the cost of minimizing concern with context.

The work of Walras was accepted relatively slowly. The mathematical problems surrounding the solution of the simultaneous equation structure of the general equilibrium model were posed in a modern mathematical context by Abraham Wald, who considered production with inputs in fixed proportion, and with a single output. He also, however, assumed the existence of demand functions rather than deriving them from utility maximization.

THE MODEL AND PROOF

The key papers presenting the first rigorous proofs of GET were written by Kenneth Arrow and Gerard Debreu (1954) and Lionel McKenzie (1959). The sketch here primarily follows the treatment presented in Debreu’s *Theory of Value* (1959).

An economy is considered initially with $l$ commodities (goods or services), $m$ utility maximizing agents, and $n$ profit maximizing multi-product firms. The economy exists over a specific finite period of time sectioned into $T$ time periods. The existence of money is not considered. It is as though there exists some vast smoothly functioning central clearinghouse that balances all accounts at the end
of the trading period after which the economy ceases. A commodity or service is characterized not merely by its physical aspects, but by both a time of availability and a location, providing a considerable simplification of the model structure. It is as though all trade takes place in a single time period, with a vast array of futures markets available that make further trade unnecessary.

All real persons or individuals are assumed to have well-defined preferences that can be represented by utility functions. It is further assumed that individual preferences are such that more goods are always of value.

Production is described by a convex production set, in which each individual producer selects a set of inputs to maximize the profits obtained from the sale of its outputs. In the process of production, free disposal is assumed. The profits are distributed to individuals who hold shares in the firms. It is proved (under reasonably plausible conditions on the utility functions and production sets) that a set of prices exist (not necessarily unique) such that supply equals demand in every market and that the resultant imputation of goods and services is efficient or Pareto optimal, meaning that there is no way that any individual can improve utility without another individual obtaining less utility. The method of proof is highly technical; it utilized fixed-point theory (Kakutani 1941), which has been of considerable use in both subsequent developments in general equilibrium theory and in the application of the theory of games in economics.

**PROBLEMS WITH THE ASSUMPTIONS AND DEVELOPMENTS IN GET**

Since the development of the original models, there have been many modifications of the original stringent assumptions. In particular, the original models deal with a finite sector of time, but in the real world there is a past and a future. There is thus a question as to how one can extend the general equilibrium analysis to infinite horizon models. Furthermore, given an infinite horizon model, an overlapping generations structure to the population appears to be more appropriate than viewing individuals as living forever. The seminal work of Maurice Allais (1946) and Paul Samuelson (1958) opened up a literature extending the investigation of competitive markets (see Geanakoplos 1987 for an extensive summary).

When dealing with a high level of abstraction, the linkage between the assumption and the underlying reality must be considered, for there are empirical exceptions to virtually every assumption made. But, on the whole, the question to be considered is whether the rigor, when confronted with the reality, provides a good enough fit to cast light on the function of a significant part of the economy. The considerable developments in the computation of applied general equilibrium models suggests that it does. The computational methods are based on the work of Herbert Scarf.

A basic assumption in the original proofs is that individual consumers and firms are "price takers." In other words, they are so small that their actions have no influence on market prices. But, as presented, the proofs were based on there being a finite number of agents. This affects the stated basic assumption of price taking. The Debreu proof does not depend on whether there is one agent or a million in any market. If this finite number is taken into account, then the actions of individual agents may influence price. A precise proof is needed to show the conditions under which the individual influence can be ignored. Robert Aumann (1964), using technical results from the mathematics of measure theory, provided a solution reflecting the lack of power of an individual small agent. The strategic market game (SMG) model of Lloyd Shapley and Martin Shubik (1977) provided the basis for non-cooperative game models of a closed economy, while Pradeep Dubey and Shubik (1978) showed the basic inefficiency of the noncooperative equilibria. However, the equilibria approach a competitive price as the number of agents in the economy increases. The noncooperative game models and the general equilibrium models are mathematically distinct, but for a continuum of agents the solutions may coincide.

The original models avoided problems with uncertainty through an ingenious but unsatisfactory enlargement of the number of goods, including a myriad of markets with contingent goods. This is currently being avoided in the development of general equilibrium with incomplete (GEI) markets.

The SMG models of the economy are more institutional than those of GET. They require an explicit specification of the price formation mechanism in the markets and a description of what happens to the traders under all circumstances. The mathematical model is so complete that it could be played as an experimental game, and the role of money and markets appears naturally and explicitly as a way of simplifying trading activity. The game-theoretic formulation has permitted the handling of three important items left out by GET: the influence of oligopolistic markets (i.e., markets with powerful players whose individual action influences price), the role of possible default, and the role of different levels of information.

At a high level of abstraction, there is an important link between work in cooperative game theory and GET. There are two cooperative game theory solutions called the core and value that can be related to the competitive equilibrium. These solutions stress group power and individual equity. The core characterizes outcomes that cannot be effectively challenged by group behavior, while the
value reflects the expected marginal productivity of an individual over all groups he or she could join. It can be shown that in an economy with many individuals the price system has the properties of both the core and the value.

WHAT LIES BEYOND?
One of the major concerns in economic theory is the reconciliation between general equilibrium microeconomic theory and macroeconomics. It has been suggested that a natural extension beyond basic general equilibrium will incorporate both the financial structure and government. The next series of basic micro-macro models will have a continuum of private agents plus government as a large player. Beyond this, the addition of taxation and public goods to the basic micro-macro models of the economy will be difficult but rewarding. Game-theoretic methods that permit the blending of price taking and oligopolistic elements, and that take into account nonsymmetries in information, are currently being developed in the study of macroeconomic control.

GENERAL MOTORS
In 2006 Detroit-headquartered auto giant General Motors (GM) was the world's largest automaker and ranked number three on the Fortune 500 list of America's largest corporations. The company has been a major player in U.S. labor history, and its vast worldwide expansion has had, and continues to have, many social consequences.

In 1897 Ransom E. Olds (1864–1950) formed the Olds Motor Vehicle Company and created several different automobile models powered by electricity and gasoline. After a fire in its factory, the company was forced to change its marketing and development strategy, which had previously focused on the wealthy, and instead moved to create a mass market for its vehicles, making them competitively priced with horses and buggies. This strategy was effective, and by 1904 the company had sold more than 12,500 vehicles.

Meanwhile, the owner of Buick was developing a complex network of suppliers to lower its costs, and incorporated with its holdings as General Motors. From 1908 to 1910 Oldsmobile, Cadillac, and several other smaller companies joined forces with the new company to create a larger, more powerful automaker. The incorporation included many more suppliers and an expansion to trucks and airplanes, and in the first half of the twentieth century, GM grew rapidly. The company also benefited from many defense contracts during World War I (1914–1918) and World War II (1939–1945).

GM's massive growth led to a need for large numbers of workers to assemble parts and automobiles. To improve their working conditions and increase their pay, workers throughout GM began to unionize in 1935 under the AFL-CIO. Later, a split in this organization led to the development of what would become one of the largest and most powerful unions in U.S. history: the United Auto Workers (UAW). The UAW was one of the first unions in the United States to include black workers.

Shortly after its formation, the UAW demanded contracts for GM autoworkers, but was denied negotiations with the automaker. On December 29, 1936, GM was informed that its largest stamping plant, in Flint, Michigan, was going to strike, and the company quickly made plans to move the machinery from the facility. In order to keep GM from removing the machinery, the workers staged a sit-down strike. Police attacked the strik-
ers with tear gas, but workers remained at the plant for forty-four days until GM signed a document recognizing the UAW as the official representative of its workers for bargaining purposes. This was a significant event in U.S. labor history, as a large corporation conceded to the demands of a union.

The unionization of autoworkers at GM helped the American middle class grow rapidly in the 1950s. Despite their blue-collar jobs, workers had salaries and benefits that allowed them the luxuries of middle-class life. Many scholars believe this change in status allowed embourgeoisement to take place; that is, working-class laborers gained middle-class values and lifestyles because of their increased wages and class position, and their support for radical political movements declined (Abercrombie et al. 2000).

GM has been criticized for corporate practices that are ecologically unsound or that violate human rights. Throughout the 1990s, there was much concern about GM’s use of factories in the developing world (especially Mexico) for cheap and less-restricted labor. According to a 1998 Human Rights Watch report, the directors of GM-run maquiladoras (foreign-owned plants that are operated by multinational corporations) in Mexico were repeatedly accused by their workers of unfair work termination and sex discrimination, especially pregnancy-related discrimination. Female employees complained that they were forced to undergo pregnancy tests before gaining employment, and some said they were even made to show their sanitary napkins to prove that they were not pregnant to retain employment. Other concerns have been raised over GM’s relationship with the environment. For example, its Hummer brand has been repeatedly cited as one of the worse violators in the consumer truck market because of its high emissions and a fuel economy of less than ten miles per gallon. A 2006 documentary, Who Killed the Electric Car, attacks GM for the systematic dismantling of its electric-car program and for what the filmmakers imply was a conspiracy between GM and the oil industry.

GENERALIZED AUTOREGRESSIVE CONDITIONAL HETEROSEDASTICITY (GARCH) MODEL

SEE Autoregressive Models.

GENERALIZED LEAST SQUARES

Generalized least squares (GLS) is a method for fitting coefficients of explanatory variables that help to predict the outcomes of a dependent random variable. As its name suggests, GLS includes ordinary least squares (OLS) as a special case. GLS is also called “Aitken’s estimator,” after A. C. Aitken (1935). The principal motivation for generalizing OLS is the presence of covariance among the observations of the dependent variable or of different variables across these observations, conditional on the explanatory variables. Both phenomena lead to problems with statistical inference procedures commonly used with OLS. Most critically, the standard methods for estimating sampling variances and testing hypotheses become biased. In addition, the OLS-fitted coefficients are inaccurate relative to the GLS-fitted coefficients.

In its simplest form, the linear model of statistics postulates the existence of a linear conditional expectation for a scalar, dependent random variable $y$ given a set of non-random scalar explanatory variables $x_1, \ldots, x_K$:

$$E[y_i] = \beta_1 x_{i1} + \ldots + \beta_K x_{iK}$$

where the $\beta_k$, $k = 1, \ldots, K$, are constant parameters for all values of the $x_i$. Interest focuses on estimating the $\beta_k$ given a sample of $N$ observations of $y_i$ denoted here by $y_{1i}, \ldots, y_{Ni}$ and corresponding observations of the $x_i$, denoted $x_{1i}, \ldots, x_{Ni}$ for each explanatory variable indexed by $k$. Using matrix notation, the linear conditional expectations for the sample are

$$E[y_i] = X\beta$$
where \( y = [y_1, \ldots, y_N]' \) is an \( N \times 1 \) column vector, \( X = [x_{nk}; n = 1, \ldots, N; k = 1, \ldots, K] \) is a \( N \times K \) matrix, and \( \beta = [\beta_1, \ldots, \beta_K]' \) is a \( K \times 1 \) column vector. It is generally assumed that the explanatory variables in \( X \) are not linearly dependent so that \( N \geq K \) and there is no \( \alpha \in \mathbb{R}^N \), \( \alpha = 0 \), such that \( X\alpha = 0 \).

In addition, the linear model assumes that the variances of the \( y_n \) are equal to a common, finite positive constant \( \sigma^2 \) and that the covariances among the \( y_n \) are equal to zero. In matrix notation, these assumptions assign to \( y \) a scalar variance-covariance matrix:

\[
\text{Var}[y] = \sigma^2 \cdot I = \begin{bmatrix} \sigma^2 & 0 & \cdots & 0 \\ 0 & \sigma^2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & \sigma^2 \end{bmatrix}
\]

where \( I \) denotes an \( N \times N \) identity matrix. The fundamental difference between such a linear model and one leading to generalized least squares is that the latter permits an unrestricted variance-covariance matrix, often denoted by

\[
\text{Var}[y] = \Sigma
\]

where \( \Sigma = [\sigma_{mn}; m, n = 1, \ldots, N] \) is an \( N \times N \) positive semidefinite matrix. In this extension of the linear model, the variances along the diagonal of \( \Sigma \) may vary across observations, and the covariances in the off-diagonal positions of \( \Sigma \) may be nonzero and may also vary across pairs of observations. In this essay, \( \Sigma \) is also assumed to be nonsingular.

Many authors refer to the generalized model as the linear model with nonspherical errors. This term derives, in part, from viewing \( y \) as the sum of \( X\beta \) and an additional, unobserved variable that is an error term. Rather than making assumptions about the observable \( y \) and \( X \) as above, these writers make equivalent assumptions about the unobserved error term. The term nonspherical refers to the type of variance-covariance matrix possessed by the error term. Multivariate distributions with scalar variance-covariance matrices are often called spherical. This term can be traced to interpreting the set

\[ \{ u \in \mathbb{R}^N | u'(\sigma^2 \cdot I)^{-1}u = 1 \} \]

as an \( N \)-dimensional sphere (or spheroid) with radius \( \sigma \). In the nonscalar case, the set

\[ \{ u \in \mathbb{R}^N | u'(\Sigma)^{-1}u = 1 \} \]

is an \( N \)-dimensional ellipsoid and distributions with nonscalar variance-covariance matrices are called nonspherical. Hence, a linear regression accompanied by a nonscalar variance-covariance matrix may be called the case with nonspherical errors.

### Examples

Leading examples motivating nonscalar variance-covariance matrices include heteroskedasticity and first-order autoregressive serial correlation. Under heteroskedasticity, the variances \( \sigma_{nt}^2 \) differ across observations \( n = 1, \ldots, N \) but the covariances \( \sigma_{ntn'} \), \( m = n \), all equal zero. This occurs, for example, in the conditional distribution of individual income given years of schooling where high levels of schooling correspond to relatively high levels of the conditional variance of income. This heteroskedasticity is explained in part by the narrower range of job opportunities faced by people with low levels of schooling compared to those with high levels.

Serial correlation arises in time-series data where the observations are ordered sequentially by the time period of each observation; \( y_n \) is observed in the \( n \)-th time period. First-order autoregressive (AR(1)) serial correlation occurs when deviations from means (also called errors) satisfy the linear model

\[
E[y_n - x_n'\beta | y_1, \ldots, y_{n-1}] = \rho(y_{n-1} - x_{n-1}'\beta), \quad n > 1,
\]

while maintaining the assumption that the marginal variance of \( y_n \) equals a constant \( \sigma^2 \). Nonzero covariances of the form

\[
\text{Cov}[y_{n-s}, y_n] = \rho \sigma^2, \quad s = 0, 1, 2, \ldots, n - 1, n > 1,
\]

are implied by the recursion

\[
\text{Cov}[y_{n-s}, y_n] = \rho \text{Cov}[y_{n-s-1}, y_{n-1}]. \quad (2)
\]

A times series of monthly unemployment rates exhibits such autoregressive serial correlation, reflecting unobserved social, economic, and political influences that change relatively slowly as months pass.

A second leading example of serial correlation occurs in panel data models, designed for datasets with two sampling dimensions, typically one cross-sectional and the other time-series. Repetitive testing of a cross-section of households. Panel data models are usually expressed in an error components form:

\[
y_{nt} = x_{nt}'\beta + \alpha_n + \varepsilon_{nt}
\]

where \( \alpha_n \) and \( \varepsilon_{nt} \) are unobserved error terms with \( E[\alpha_n] = 0 \) and \( \text{Var}[\alpha_n] = \sigma_{\alpha}^2 \), \( \text{Var}[\varepsilon_{nt}] = \sigma_{\varepsilon}^2 \), and \( \text{Cov}[\alpha_n, \varepsilon_{nt}] = 0 \), \( \text{Cov}[\varepsilon_{nt}, \varepsilon_{nt'}] = 0 \) for all \( m, n, j = 1, \ldots, N, t, s = 1, \ldots, T; \) and \( n \neq j, t \neq s \). The \( \alpha_n \) are individual effects that recur for all observations of a particular individual and they induce serial correlation:

\[
\text{Cov}[y_{nt}, y_{nt}] = \sigma_{\alpha}^2
\]

for \( m = n \) and \( t \neq s \). Unlike the AR(1) case, this covariance does not diminish as the time between observations...
increases. Instead, all of the observations for an individual are equally correlated.

Correlation also occurs in cross-sectional data. In the seemingly unrelated regressions (SUR) setting, there are several dependent variables and corresponding mean functions:

\[ E[y_{ng}] = x'_n \beta_g, \quad g = 1, \ldots, G. \]

Such dependent variables are typically related as different characteristics of a single experiment or observational unit. For example, the \( y_{ng} \) might be test scores for substantively different tests written by the same individual. Even after accounting for observable differences among the tests and test takers with \( x_{ng} \) covariance among the test scores may reflect the influence of unobserved personal abilities that affect all of the tests taken by a particular person. Alternatively, the \( y_{ng} \) could be total income in countries during the same time period so that neighboring states possess similar underlying characteristics or face similar environments that induce covariance among their incomes.

**STATISTICAL ISSUES**

The general linear model motivates two principal issues with statistical inferences about \( \beta \) in the simpler linear model. First, hypothesis tests and estimators of sampling variances and confidence intervals developed under the linear model are biased when \( \Sigma \) is not scalar. Second, the OLS estimator for \( \beta \) generally will not be the minimum-variance linear unbiased estimator. The OLS estimator

\[
\hat{\beta}_{OLS} = \arg \min_{b \in \mathbb{R}^p} \langle y - Xb \rangle'(y - Xb)
= (X'X)^{-1}X'y
\]

is a linear (in \( y \)) and unbiased estimator when \( \Sigma \) is not scalar. However, its sampling variance is

\[
\text{Var}[\hat{\beta}_{OLS}] = (X'X)^{-1}X'\Sigma X(X'X)^{-1}
\]

which is generally not proportional to \((X'X)^{-1}\), an outcome implied by the simple linear model. When \( \Sigma \) is nonsingular, the GLS estimator

\[
\hat{\beta}_{GLS} = \arg \min_{b \in \mathbb{R}^p} \langle y - Xb \rangle'\Sigma^{-1}(y - Xb)
= (X'\Sigma^{-1}X)^{-1}X'\Sigma^{-1}y
\]

is the minimum-variance linear and unbiased estimator. Its variance-covariance matrix is

\[
\text{Var}[\hat{\beta}_{GLS}] = (X'\Sigma^{-1}X)^{-1}.
\]

GLS can be understood as OLS applied to a linear model transformed to satisfy the scalar variance-covariance restriction. For every \( \Sigma \), one can always find a matrix \( A \) such that \( \Sigma = AA' \). We will give some examples shortly. Given such an \( A \), it follows that

\[
\text{Var}[A^{-1}y] = A^{-1}\text{Var}[y]A^{-1} = A^{-1}\Sigma A^{-1} = I
\]

or, in words, that \( \tilde{\beta} = A^{-1}y \) has a scalar variance-covariance matrix. At the same time,

\[
E[A^{-1}y] = A^{-1}EX = A^{-1}X\beta
\]

so that the expectation of the transformed \( y \) has corresponding transformed explanatory variables \( \tilde{X} = A^{-1}X \). Applying OLS to estimate \( \beta \) with the transformed variables yields the GLS estimator:

\[
\left(X'X\right)^{-1}\tilde{X}'\tilde{y} = \left((A^{-1})'A^{-1}X\right)^{-1}\left((A^{-1})'A^{-1}X\right)A^{-1}y
= \left(X'(A^{-1})'A^{-1}X\right)^{-1}X'(A^{-1})'A^{-1}y
= \left(X'\Sigma^{-1}X\right)^{-1}X'\Sigma^{-1}y
\]

because \( \Sigma^{-1} = (A^{-1})'A^{-1} \). In a similar fashion, one sees that the OLS criterion function is transformed into the GLS criterion function:

\[
\langle y - X\tilde{b} \rangle'(y - X\tilde{b}) = \langle y - Xb \rangle'(y - Xb).
\]

Heteroskedasticity produces a simple example. To produce observations with equal variances, each data point is divided by the standard deviation

\[
\sigma_n = \sqrt{\text{Var}[y_n]}:
\]

\[
\text{Var}[y_n] = \frac{1}{\sigma_n^2} \text{Var}[\bar{y}_n] = \frac{1}{\sigma_n^2} \sigma_n^2 = 1.
\]

This corresponds to choosing \( A^{-1} \) equal to a diagonal matrix with the reciprocals of these standard deviations arrayed along its diagonal. The estimation criterion function is

\[
\sum_{n=1}^{N} \frac{(y_n - x'_n b)^2}{\sigma_n^2}
\]

which is a weighted sum of squared residuals. For this reason, in this special case GLS is often called weighted least squares (WLS). WLS puts most weight on the observations with the smallest variances, showing how GLS improves upon OLS, which puts equal weight on all observations. Those \( n \) for which \( \sigma_n \) is relatively small tend to be closest to the mean of \( y_n \) and, hence, more informative about \( \beta \).

Faced with AR(1) serial correlation in a time series, the appropriate choice of \( A \) transforms each data point (except the first) into differences:

\[
\tilde{y}_n = y_n - \rho y_{n-1},
\]

\[
\tilde{x}_{nk} = x_{nk} - \rho x_{n-1,k}, \quad k = 1, \ldots, K.
\]
This transformed $\tilde{y}_n$ display zero covariances:

$$\text{Cov}[y_{n-1} - \rho y_{n-1}, y_n - \rho y_{n-1}]$$

$$= \text{Cov}[y_{n-1}, y_n] - \rho \text{Cov}[y_{n-1}, y_{n-1}]$$

$$- \rho \text{Cov}[y_{n-1}, y_n] + \rho^2 \text{Cov}[y_{n-1}, y_{n-1}]$$

$$= \rho \text{Cov}[y_{n-1}, y_{n-1}] - \rho \text{Cov}[y_{n-1}, y_{n-1}]$$

$$- \rho^2 \text{Cov}[y_{n-1}, y_{n-1}] + \rho^2 \text{Cov}[y_{n-1}, y_{n-1}]$$

$$= 0$$

using (2) for the first and third terms on the right-hand side. This transformation uncovers the new or additional information available in each observation, whereas OLS treats highly correlated observations the same way as uncorrelated observations, giving the former relatively too much weight in that estimator.

The panel data model has a simple GLS transformation as well:

$$\tilde{y}_{nt} = y_{nt} - (1 - \omega)\tilde{y}_n,$$

$$\tilde{x}_{ntk} = x_{ntk} - (1 - \omega)\tilde{x}_{nk}, \quad k = 1, \ldots, K$$

where $\tilde{y}_n$ and $\tilde{x}_{nk}$ are the individual averages over time $\sum_{n=1}^{N} y_{nt} / T$ and $\sum_{n=1}^{N} x_{ntk} / T$, respectively, and

$$\omega = \frac{\sigma_\varepsilon}{\sqrt{\sigma_\alpha^2 + \sigma_\varepsilon^2}}.$$ 

If there is no serial correlation, then $\sigma_\alpha = 0$ and $\tilde{y}_n = y_{nt}$. Conversely, the greater $\sigma_\alpha$ is, the more important the individual average $\tilde{y}_n$ becomes. Like the AR(1) case, a weighted difference removes the covariance among the original $y_{nt}$. In this case, however, a common time-series sample average appears in every difference, reflecting the equal covariance structure.

Note that the GLS estimator is an instrumental variables (IV) estimator,

$$\hat{\beta}_{IV} = (Z'X)^{-1}Z'y,$$

for an $N \times K$ matrix $Z$ of instrumental variables such that $Z'X$ is invertible. For GLS, $Z = \Sigma^{-1}X$. Researchers use instrumental variables estimators to overcome omission of explanatory variables in models of the form

$$y = x'\beta + \varepsilon$$

where $\varepsilon$ is an unobserved term. Even though $\text{E}[\varepsilon] = 0$, correlation between the explanatory variables in $x$ and $\varepsilon$ biases $\hat{\beta}_{OLS}$ and the IV estimator is employed to overcome this bias by using instrumental variables, the variables in $Z$, that are uncorrelated with $\varepsilon$ yet correlated with the explanatory variables. In some cases of the linear model, the GLS estimator provides such instrumental variables. If, for example, $x_n$ includes the lagged value of $y_n$ in a time-series application, then residual serial correlation usually invalidates the OLS estimator while GLS still produces an estimator for $\beta$.

In the panel data setting, particular concern about the behavior of the unobserved individual effect $\alpha_n$ has led researchers to compare the GLS estimator with another IV estimator. The concern is that the expected value of $\alpha_n$ may vary with some of the observed explanatory variables in $x_{nt}$. Various observable characteristics of individuals or households are typically correlated so that one would expect the unobserved characteristics captured in $\alpha_n$ to be correlated with the observed characteristics in $x_{nt}$ as well.

In this situation, the OLS- and GLS-fitted coefficients are not estimators for $\beta$ because these fitted coefficients pick up the influence of the $\alpha_n$ omitted as explanatory variables. An IV estimator of $\beta$ that is robust to such correlation is the so-called fixed effects estimator. This estimator is often described as the OLS fit of $y_{nt} - \tilde{y}_n$ to the explanatory variables $x_{ntk} - \tilde{x}_{nk}, \quad k = 1, \ldots, K$, but an equivalent IV estimator uses the instrumental variables $z_{ntk} = x_{ntk} - \tilde{x}_{nk}$.

In the special case when $\omega = 0$, the fixed effects and GLS estimators are equal. The GLS estimator is often called the random effects estimator in this context, and the difference between the fixed-effects and random-effects estimators is often used as a diagnostic test for the reliability of GLS estimation (Hausman 1978).

The OLS and GLS estimators are equal for a general $\Sigma$ if the GLS instrument matrix $\Sigma^{-1}X$ produces the same set of fitted values as the explanatory variable matrix $X$. Formally, $\hat{\beta}_{OLS} = \hat{\beta}_{GLS}$ if and only if every vector $X_\alpha, \quad \alpha \in \mathbb{R}^K$, equals $\Sigma^{-1}X_\gamma$ for some $\gamma \in \mathbb{R}^K$, and vice versa. A practical situation in which this occurs approximately is when AR(1) serial correlation is accompanied by explanatory variables that are powers of $n$ or trigonometric functions of $n$. Another example arises when all covariances are equal (and not necessarily zero) and the regression function includes an intercept (or constant term), as it usually does. A third example is the case of SUR where the explanatory variables are identical for all equations, so that $x_{mg} = x_n, \quad g = 1, \ldots, G$.

**FEASIBLE METHODS**

Feasible inference for $\beta$ in the general linear model typically must overcome that $\Sigma$ is unknown. There are two popular strategies: (1) to specify $\Sigma$ as a function of a few parameters that can be replaced with estimators, and (2) to use heteroskedasticity-consistent variance estimators.

The AR(1) serial correlation model illustrates the first approach. A natural estimator for the autocorrelation parameter $\rho$ is the fitted OLS coefficient $\hat{\rho}$ for predicting the OLS-fitted residual $y_n - \tilde{y}_n$ with the single
explanatory variable \( y_{n-1} - \mathbf{x}'_{n-1} \hat{\beta}_{OLS} \), the lagged OLS-fitted residual:

\[
\hat{\beta} = \frac{\sum_{n=2}^{N} (y_{n-1} - \mathbf{x}'_{n-1} \hat{\beta}_{OLS})(y_{n} - \mathbf{x}'_{n} \hat{\beta}_{OLS})}{\sum_{n=2}^{N} (y_{n-1} - \mathbf{x}'_{n-1} \hat{\beta}_{OLS})^2}.
\]

Under certain conditions, this \( \hat{\beta} \) can replace \( \beta \) in \( \Sigma(\beta) \) to estimate the variance-covariance matrix of \( \hat{\beta}_{OLS} \), as in \((\mathbf{X}' \Sigma^{-1} \mathbf{X})^{-1}\)

where \( \hat{\Sigma} = \Sigma(\hat{\beta}) \), or to compute the feasible GLS (FGLS) estimator

\[
\hat{\beta}_{FGLS} = (\mathbf{X}' \hat{\Sigma}^{-1} \mathbf{X})^{-1} \mathbf{X}' \hat{\Sigma}^{-1} y.
\]

Similarly, one estimates the variance-covariance matrix of \( \hat{\beta}_{FGLS} \) with \((\mathbf{X}' \hat{\Sigma}^{-1} \mathbf{X})^{-1}\). In large samples, the differences between the feasible and infeasible versions are negligible. In small samples, many researchers use an estimator that requires iterative calculations to find a \( \hat{\beta} \) and \( \hat{\Sigma} \) that are mutually consistent: The fitted residuals produced by \( \hat{\beta} \) yield \( \hat{\beta} \) and the variance-covariance matrix produced by \( \hat{\rho} \) yields \( \hat{\beta} \) as the fitted FGLS coefficients. Maximum likelihood estimators, based on an additional assumption that the \( y_n \) possess a joint multivariate normal distribution, are leading examples of such estimators.

We will use the pure heteroskedasticity case to illustrate heteroskedasticity-consistent variance estimators. The unknown term in the \( \text{Var}[\hat{\beta}_{OLS}] \) (shown in (3)) can be written as a sample average:

\[
\frac{1}{N} \cdot \mathbf{X}' \Sigma \mathbf{X} = \sum_{n=1}^{N} \frac{1}{N} \sigma_n^2 \cdot x_n x_n'
\]

where \( \sigma_n^2 = \sigma_{w_n} \) is the \( n \)th diagonal element of \( \Sigma \). In a heteroskedasticity-consistent variance estimator this average is replaced by

\[
\sum_{n=1}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta}_{OLS})^2 \cdot x_n x_n'
\]

so that the unknown variances \( \sigma_n^2 \) are replaced by the squared OLS fitted residuals. Such estimators do not require a parametric model for \( \Sigma \) and, hence, are more widely applicable. Their justification rests, in part, on

\[
E[(y_n - x_n' \hat{\beta})^2] = \sigma_n^2
\]

so that one can show that

\[
\sum_{n=1}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta})^2 \cdot x_n x_n'
\]

is a valid estimator for \( \frac{1}{N} \mathbf{X}' \Sigma \mathbf{X} \). The feasible heteroskedasticity-consistent variance estimator replaces the unknown \( \beta \) with its estimator \( \hat{\beta}_{OLS} \). This variance-covariance estimator is often called the “Eicker-White estimator,” for Friedjhelm Eicker and Halbert White.

The heteroskedasticity-consistent variance estimator does not yield a direct counterpart to \( \hat{\beta}_{FGLS} \). Nevertheless, estimators that dominate OLS are available. The transformed linear model

\[
E[Z'y] = Z'X\hat{\beta}
\]

has a corresponding variance-covariance matrix

\[
\text{Var}[Z'y] = Z'\Sigma Z
\]

which has a heteroskedasticity-consistent counterpart

\[
\hat{\Omega} = \sum_{n=1}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta}_{OLS})^2 \cdot z_n z_n'
\]

and the FGLS analogue

\[
\hat{\beta}_C = \frac{(Z'X'\hat{\Omega}^{-1} ZX')^{-1}(Z'X') \hat{\Omega}^{-1} Z' y}{(Z'Z\hat{\Omega}^{-1} ZX')^{-1} X'Z\hat{\Omega}^{-1} Z' y}.
\]

This estimator reduces to OLS if \( Z = \mathbf{X} \) and produces superior estimators to the extent that \( \hat{\Sigma}^{-1} \mathbf{X} \) provides a better linear predictor of \( \Sigma^{-1} \mathbf{X} \) than \( \Sigma^{1/2} \mathbf{X} \) does.

The heteroskedasticity-consistent variance estimator has been extended to cover time-series cases with nonzero covariances as well. For example, if only first-order covariances are nonzero then

\[
\frac{1}{N} \cdot \mathbf{X}' \Sigma \mathbf{X} = \sum_{n=1}^{N} \frac{1}{N} \sigma_n^2 \cdot x_n x_n'
\]

\[
+ \sum_{n=2}^{N} \frac{1}{N} \sigma_{n,n-1} (x_n x_{n-1} + x_{n-1} x_n)
\]

because \( \sigma_{n,n-j} = 0 \) for \( j > 1 \). This term in the OLS variance-covariance matrix can be estimated by

\[
\hat{\Sigma}_{HAC} = \sum_{n=1}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta}_{OLS})^2 \cdot x_n x_n'
\]

\[
+ \sum_{n=2}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta}_{OLS}) (y_{n-1} - x_{n-1}' \hat{\beta}_{OLS}) (x_n x_{n-1} + x_{n-1} x_n'),
\]

a heteroskedasticity and autocorrelation consistent (HAC) variance-covariance matrix estimator. This works because the second average behaves much like the first in that

\[
E[(y_n - x_n' \hat{\beta})(y_{n-1} - x_{n-1}' \hat{\beta})] = \sigma_{n-1,n}
\]

so that one can show that

\[
\sum_{n=1}^{N} \frac{1}{N} (y_n - x_n' \hat{\beta})(y_{n-1} - x_{n-1}' \hat{\beta}) \cdot (x_n x_{n-1} + x_{n-1} x_n')
\]

is an estimator for the second term.
One can extend the HAC approach to cover $m$-dependence in which only $m$th-order covariances are nonzero for a finite $m$. However, in practice $m$ should be small relative to the number of observations $N$. To illustrate the difficulties with large $m$, consider setting $m = N - 1$ so that all of the covariances in $\Sigma$ are replaced by a product of OLS-fitted residuals. Then this approach yields the estimator

$$
\frac{1}{N} \cdot \mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}_{OLS})(\mathbf{y} - \mathbf{X}\hat{\beta}_{OLS})' \mathbf{X}
$$

$$
= \frac{1}{N} \cdot \mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}_{OLS})(\mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}_{OLS})')
$$

which is the outer product of the $K \times 1$ column vector $\mathbf{X}'(\mathbf{y} - \mathbf{X}\hat{\beta}_{OLS})$. It follows that this matrix has a rank of one, contradicting the property that $\mathbf{X}'\Sigma\mathbf{X}$ has a rank of $K$. Nevertheless, the heteroskedasticity-consistent variance-covariance estimator has been generalized to cover situations where all of the covariances may be nonzero. The Newey-West estimator is a popular choice:

$$
\hat{\Omega}_0 + \sum_{j=1}^{m} w(j, m) \cdot (\hat{\Omega}_j + \hat{\Omega}_j')
$$

where

$$
\hat{\Omega}_j = \sum_{n=j+1}^{N} (y_n - x'_n\hat{\beta})(y_{n-j} - x'_{n-j}\hat{\beta}) \cdot x_nx'_{n-j}
$$

and

$$
w(j, m) = 1 - \frac{j}{m+1}.
$$

The supporting approximate distribution theory requires $m$ to depend on the sample size $N$ and methods for choosing $m$ are available.

Often statistical inference for $\beta$ based upon estimation of $\Sigma$ or $\mathbf{X}'\Sigma\mathbf{X}$ can treat these terms as equal to the objects that they estimate. For example, the statistical distribution theory typically shows that

$$
Q = (\hat{\Sigma}_{GLS} - \Sigma)'(\mathbf{X}'\Sigma^{-1}\mathbf{X})^{-1}R^{-1}(\hat{\Sigma}_{GLS} - \Sigma)
$$

is approximately (or exactly) distributed as a chi-squared random variable. This pivotal statistic yields a hypothesis test or confidence interval for $\beta$. In large samples,

$$
\hat{Q} = (\hat{\Sigma}_{FGLS} - \Sigma)'(\mathbf{X}'\hat{\Sigma}^{-1}\mathbf{X})^{-1}R^{-1}(\hat{\Sigma}_{FGLS} - \Sigma)
$$

may be treated as an equivalent statistic. Researchers have shown that bootstrap methods, appropriately applied, can provide better probability approximations in situations with small sample sizes.

SEE Method of Moments.

GENERATION X

Throughout U.S. history, social commentators and historians have labeled each succeeding generation in an attempt to capture the defining characteristics of its members as well as to contextualize the generation within the spirit of the times. Generation X is the label used to define the more than 79 million people born roughly between 1961 and 1981. Although both social scientists and marketers employ this tag, the U.S. mainstream media gets credit for skyrocketing this label into our popular culture lexicon, particularly throughout the 1990s.

The term, however, was coined decades earlier in a 1964 pop sociology study conducted by two British journalists, Charles Hamblett and Jane Deverson, who used the term to describe their subjects—British teens—whom they interviewed on matters of sex, money, parents, and politics. In 1976 Generation X, a British punk band featuring Billy Idol, hit the London scene. The term eventually worked its way—via the media—into American
popular vernacular after the release of Douglas Coupland's 1991 novel *Generation X: Tales for an Accelerated Culture*, a bleak social commentary by three twenty-somethings who “drop out” from their corporate-world careers to take on no-future “McJobs” that provide little pay, benefits, or dignity. Immediately, Gen Xers—subsequently referred to as “slackers” — were officially characterized as lazy, laconic, and unfocused; however, many took issue with this assessment, describing themselves as diverse, independent, and individualistic.

The members of Generation X are arguably natural products of the intellectual atmosphere in which they grew up, for they are the first generation to be raised in the age of postmodernism—a widespread cultural development of the last quarter of the twentieth century. This paradigm shift marked a generational difference between Generation X and their baby boomer parents. Understanding the transition from modern to postmodern culture is necessary to understanding Gen Xers. Whereas modernism values a single worldview rooted in objective science, postmodernism values multiple worldviews based on subjective experiences and contingencies. Information and knowledge are gathered in a linear fashion by modernists, but Gen Xers seek out information from fragmented and nonlinear sources, such as hyper-text, visuals, and audio sampling. Whereas the modernists revere classical art and literature, postmodernists broaden their frame of reference to include pop-culture productions such as music videos and animation. Institutions such as government, education, corporations, and media, which are seen as authoritative by modernists, are viewed with a critical eye by members of Generation X.

The civil unrest of the late 1960s and early 1970s, followed by the overconsumption of the 1980s, provided the background to the 1990s—a decade laden with social problems. Violent crime, environmental degradation, widespread homelessness, spikes in teen pregnancies and suicides, corrupt politics, and the AIDS epidemic, coupled with fundamental changes in the family unit caused by rising divorce rates and dual-working parents, were the realities in which Generation X came of age. Many Xers resented the baby boomers for leaving them to repair or endure a society seemingly gone mad.

Despite the initially dismissive media portrayals and self-proclaimed cynicism about the condition of the world in which they came of age, most members of Generation X—who have reached adulthood—have learned to cope. They, like all preceding generations, are striving to attain or maintain the American Dream, albeit in different ways from the methods of their predecessors.

**GENEROSITY/SELFISHNESS**

Researchers at the National Institute of Neurological Disorders and Stroke, working on a new collaborative project with the National Institute on Mental Health and the National Institute on Aging (*Cognitive and Emotional Health Project: The Healthy Brain*) have discovered that there is a physiological basis for the warm glow that seems often to accompany altruistic giving. Nineteen subjects were each given $128 and told to donate it anonymously to any of a number of socially controversial causes, ranging from support for abortion rights to opposition to the death penalty. Subjects could accept or reject each charity, some of which would require more of their $128 pots than others. Functional magnetic resonance imaging (fMRI) revealed that making a donation activated the donors’ brain reward centers, the mesolimbic pathways responsible for the dopamine-mediated euphoria associated with sex, money, food, and drugs (Moll et al. 2006).

We should not be surprised to learn that people feel good when they do good. Group selection theory in evolution shows that groups that are strong in internal altruism have a selective advantage over other groups (Sober and Wilson 1998). Thus, it makes evolutionary sense that helping behavior within groups would be connected with stimulating feelings of well-being. On the genetic level, it appears that altruism is associated with the dopamine D4 receptor (Bachner-Melman et al. 2005).

The psychological benefits of helping others may have been demonstrated first in the early 1980s. “Well-being” is characterized by feeling hopeful, happy, and good about oneself, as well as energetic and connected to others. In an early study that compared retirees over age 65 who volunteered with those who did not, volunteers scored significantly higher in life satisfaction and will to live, and had fewer symptoms of depression, anxiety, and somatization (Hunter and Lin 1981). More recent studies confirm an association between altruistic activities and well-being and life satisfaction in older adults (Dulin and Hill 2003; Liang et al. 2001; Morrow-Howell et al. 2003). Midlarsky (1991) found five benefits to older adults who engage in altruistic behavior: enhanced social integration;
distraction from the agent’s own problems; enhanced meaningfulness; increased perception of self-efficacy and competence; and improved mood and/or more physically active lifestyle. Midlarsky and Kahana (1994) associated adult altruism—that is, voluntary behavior that is “motivated by concern for the welfare of the other, rather than by anticipation of rewards” (p. 11)—with improved morale and self-esteem, positive affect, and well-being. The mental health benefits of giving in the form of volunteerism—a wider form of giving than charitable donation—include fewer depressive symptoms (Musick and Wilson 2003) and greater happiness and well-being (Krueger et al. 2001).

In his book *The Happiness Hypothesis* (2006), Jonathan Haidt, a social psychologist at the University of Virginia, discusses great ancient ideas about human flourishing—that is, what makes for a happy and meaningful human life. Haidt explains how the human system of attachment has evolved and how important it is to our successful development, emphasizing Emile Durkheim’s idea that the ties, bonds, and obligations of our lives are actually mentally and physically good for us. Helping others provides more benefits than receiving help, and strong social relationships increase immunity, speed healing, and reduce the risks of depression. It makes sense that volunteering appears to be most beneficial to the elderly—both because of the increased social isolation of this life stage, and because giving back fits particularly well into the end-of-life story (Haidt 2006).

In a literature review on the relationship between volunteering and psychological health, “Doing Well by Doing Good: Benefits for the Benefactor” (2003), Jane Piliavin narrows the review by including only studies of community service, defined as “taking actions, carried out within an institutional framework, that potentially provide some service to one or more other people or to the community at large” (p. 227). The studies are organized by the life-cycle stage of the participants (e.g., youth, adult, and elderly), reflecting the belief that volunteering plays different roles, and therefore has different effects, depending on the age of the volunteer. Most studies have focused on the youth stage, when the first opportunities to volunteer arise, and the elderly stage, when volunteering may replace important family and work roles as a source of identity and self-esteem. After reviewing numerous studies of adolescents and college students, Piliavin concludes that there is “considerable evidence that community service has positive impacts on youth” (p. 235). The studies have shown decreased delinquency and other problem behaviors, as well as positive impacts on social values and academic achievements. Studies on service learning—“academic experiences in which students engage both in social action and in reflection on their experiences in performing that action” (p. 236)—have revealed positive effects on self-esteem, confidence, and self-efficacy, particularly for at-risk students. The comparatively vast literature on volunteering in elderly populations has perhaps contributed the most to the idea that doing good is good for you. Piliavin reviewed studies investigating impacts on mental health, morbidity, and mortality and concluded that “there appears to be a strong and consistent effect, such that the more an elderly person volunteers, the higher is his or her life satisfaction … similarly, some volunteering enhances physical health and even can stave off death” (p. 241).

Genetic Testing

Stephen G. Post

GENETIC TESTING

The term genetic testing refers to the molecular analysis of DNA for genetic markers associated with particular genetic conditions, to tests for enzymes or proteins related to gene function, and to chromosomal analysis. Social science studies of genetic testing practices and their social and cultural implications involve, for example, considerations of community, family, kinship, and health and address issues such as informed consent, intellectual property rights, and privacy. Critical assessments of screening and testing practices and of the interpretations of genetic information illuminate the normative effects and premises, past and present, that occur both in institutional settings and in everyday life and are reflected in policy.

PRENATAL DIAGNOSTIC TESTING

One of the earliest and most enduring areas of social science research on genetic testing concerns the social implications of prenatal diagnostic testing (PND). PND involves genetic testing during pregnancy for genetic conditions and chromosomal anomalies in the developing fetus using practices such as chorionic villus sampling (testing placental blood cells) and amniocentesis (testing fetal cells from amniotic fluid). Studies of prenatal diagnostic testing have illustrated the influence it has on experiences of pregnancy, conceptualizations of disability, mediations of genetic information, and knowledge and performances of parental and civil responsibility. Barbara Katz Rothman’s The Tentative Pregnancy: How Amniocentesis Changes the Experience of Motherhood (1986) was among the first studies following the introduction of amniocentesis (at that time done between sixteen and twenty weeks) to illustrate the complexity of women’s experiences of mediating the possibility of undergoing the test, abortion, and/or results indicating a possible disability during the first four to five months of pregnancy. By the late 1990s, amniocentesis had become a routine testing possibility during pregnancy, concurrent with the emergence of an understanding of the fetus as patient (Casper 1998). Published in 1999, Rayna Rapp’s book Testing Women, Testing the Fetus speaks to the duality of women and fetuses as the subjects of prenatal testing. Employing a multi-sited approach, including research with lab technicians, genetic counselors, and pregnant women, Rapp explores the meanings of amniocentesis within this shifting context. Critical decisions stemming from the availability of PND involve the interpretation of genetic information and embodied experience by medical practitioners, genetic counselors, lab technicians, and prospective parents.

In 1989 the first child born as a result of the application of preimplantation genetic diagnosis (PGD), involving the molecular analysis of one or two cells taken from an embryo created by in vitro fertilization prior to transferring the embryo to a woman’s uterus, was reported. In most cases, PGD involves tests for specific genetic mutations, which are offered on the basis of an understanding that one or both potential parents (or egg or sperm donor) is a carrier of a genetically inheritable condition or has a prior history of having a child with a genetic condition. In common parlance and media coverage, children born following PGD have been called designer babies, a term referring to the growing potential to influence the genetic make-up of one’s child and reflecting concerns over the procedure’s implications for social perceptions of normalcy and disability. Aneuploidy screening, generally testing embryos for chromosomal anomalies rather than for specific genetic mutations, is referred to as preimplantation genetic screening (PGS), rather than PGD.

In 2000 Adam Nash became the first child reported to be born as a result of the use of PGD not only for the purpose of selecting out embryos with a particular genetic marker, but also for selecting in embryos whose HLA tissue type directly matches that of an already existing sibling, rendering the child-to-be a compatible stem cell donor. In the media, such children have been referred to as savior siblings, invoking associations with sacrifice as well as life-saving. The use of PGD, or PID as it is sometimes called, is banned in many countries (for example, Germany) and restricted to use in relation to particular genetic conditions in others (for example, the United Kingdom).

Preimplantation genetic diagnosis is also applied to test embryos for late-onset disorders and genetic susceptibility to particular conditions, including Huntington’s disease, breast cancer, and hereditary colon cancer. Debates in this area highlight the perceptions and cultural management of “genetic risk status” in relation to disorders with variable degrees of penetrance (or the degree to which the genetic mutation corresponds to the manifestation of the condition) and for which preventative measures or treatment may be available. For example, the genetic mutation associated with Huntington’s disease is highly penetrant, corresponding to an expected certainty of developing the disease over the course of a lifetime. In contrast, the mutations on the BRCA 1 and BRCA 2 genes, associated with hereditary forms of breast cancer (accounting for 5 to 10 percent of breast cancer cases), have a penetrance level of approximately 80 percent. This
means that not everyone who carries the BRCA 1 and BRCA 2 gene mutations will develop breast cancer in their lifetime and that the likelihood of developing this form of breast cancer increases with age.

PREDICTIVE GENETIC TESTING

The term predictive genetic testing (PGT) refers to testing that occurs prior to the appearance of symptoms. It is used in situations where there is a known history of a perceived genetic condition among genetically related individuals. While issues involving the individual are often the focus of studies of genetic testing—for example, the autonomy of the individual to make an informed decision regarding a test and follow-up actions or the specificity and uniqueness of an individual’s “genetic code”—social science research on PGT provides critical data and insight into the construction and experience of hereditary risk and the familial and social context of genetic testing. In the case of testing for genetically inherited mutations, testing may require the prior or parallel testing of a family member and the communication of their potential genetic risk status. Results of genetic tests for one family member may implicate the “risk” status of other genetically related family members, who may or may not choose to undergo genetic testing.

The Human Genome Project, which ran from 1991 to 2003, resulted in the identification of increasing numbers of specific genes and genetic mutations implicated in genetic conditions, as well as the function of enzymes and proteins. There is increasing emphasis placed on the use of predictive genetic testing among a broader population with no prior awareness or familial history of specific genetic conditions. This form of predictive testing is proposed with respect to the implementation of preventative measures and personalized medicine. Routine genetic screening, for example of newborns for cystic fibrosis, raises additional questions regarding the disclosure and use of information about the gene carrier status of individuals, as well as about potential implications for individuals who did not consent to genetic testing. While in many cultural contexts, predictive testing of children is advised against, research demonstrates that testing occurs and, in the name of preventative medicine, is promoted. The availability of genetic tests and their use on a broader scale raises concerns regarding genetic discrimination, specifically in the areas of health insurance and employment.

The field of pharmagenomics (sometimes referred to as personalized medicine) focuses on the development of medical and preventative care tailored to an individual’s genetic makeup. In 2005 the U.S. Food and Drug Agency approved the use of BiDil, a post-heart-attack drug treatment marketed by NitroMed, for black individuals following a clinical trial exclusively involving self-identifying black patients. Because women of Ashkenazi Jewish descent are seen to have a significantly higher percentage of mutations at particular points along the BRCA 1 and BRCA 2 genes, in some jurisdictions they may be given access to breast cancer gene testing without the involvement of another living family member with breast cancer, which is often otherwise required. This relationship between genetic testing and ethnic identification has manifested differently in Europe, where in 2005 Myriad Genetics won the right to a patent on a particular mutation associated with the Ashkenazi Jewish population, requiring physicians to ask breast cancer gene test candidates whether they are of Ashkenazi Jewish descent. While variations in the manifestation, management, and recognition of various conditions have been recognized in comparative and cross-cultural studies of health, reducing these variations to genetic difference runs the risk of reifying and geneticizing concepts such as race and ethnicity and obscuring social determinants of health.

The turn toward genomics, the study of the interaction between genes and the environment, has resulted in the implementation of biobanks, or population genetic databases, as genetic research resource centers. Members of communities and nation-states are requested to donate blood (DNA) samples for research purposes. When genetic testing is conducted within the framework and for the purpose of health care, there is a normative expectation that individuals are aware of the tests being carried out and also of how resulting genetic information will be managed. Studies of biobanking reveal, however, that research participants (those who donated DNA samples) do not have a clear idea of what will be done with the sample or the information derived from it and are not aware of whom it could be distributed to or for how long it will be retained (see Hoeyer 2003). Children are also being included as participants in larger genomic studies, enrolled at birth via the donation of umbilical cord blood by consenting parents.

The advent of genetic testing in the form of PND, PGD, predictive testing, and population-based genetic research is captured by the phrase new genetics, within which is embedded a distinction from eugenics and other previous uses and abuses of genetics. Whereas eugenics is depicted as the imposition on individuals of decisions made by states or other authorities, the new genetics is associated with choice, information, knowledge, autonomy, and responsibility. Social science research and analysis of the new genetics is needed in order to address, for example, how concepts of normalcy are mobilized in new ways, how new forms of genetic information may lead to present and future discrimination, and how concepts such as reproductive choice and civil responsibility are experienced in the context of increasing emphasis on the signifi-
icance of genetic information, genetic health, and genetic research.

GENEVA CONVENTION

SEE War Crimes.

GENOCIDE

Genocide is one of the foundational moral, legal, and political concepts of modern society. While the terrible suffering named by the term is not new, the meaning of genocide is intimately bound to the creation of the modern human rights movement in the wake of World War II (1939–1945) and the subsequent evolution and expansion of new mechanisms of global governance.

Genocide is a term of profound moral, legal, and political significance. On moral terms, genocide references extreme inhumanity, naming a boundary where the central tenets of civilized behavior are called into question by the most reprehensible acts of political violence. Legally, genocide is understood as a crime whose severity demands immediate and total condemnation. As the special rapporteur to the UN Economic and Social Council Commission on Human Rights stated, "Genocide is the ultimate crime and the gravest violation of human rights it is possible to commit" (1985, part I, para. A14).

Politically, the term helped establish the foundations of modern human rights discourse and practice. The United Nations began discussing genocide in its first year of operation (1946), and the Convention for the Prevention and Punishment of the Crime of Genocide (Genocide Convention), entered into force in 1951, was the first legally binding international human rights convention. In these interconnected ways, genocide represents a major element of an evolving human rights consciousness as well as a growing global commitment to protecting people from harm and preventing the worst excesses of the exercise of power.

Throughout human history, there are records of massacres and violence directed toward the destruction of entire peoples. References of mass violence that might be termed genocide can be found in the Bible, the works of the ancient Greeks and Romans, the religious-military campaigns of the Middle Ages, and the mass killing of indigenous peoples in the Americas, Africa, and elsewhere associated with "discovery" and colonization. The modern discussion of the concept is often associated with Turkish atrocities against the Armenians (1915–1923), when as many as 1.5 million may have been killed. However, it was the Nazi atrocities of the Holocaust that led to the evocation of genocide as a distinct crime, in which over 6 million Jews were exterminated in a systematic and calculated manner, along with Roma, Slavs, and other groups viewed to be dangerous or undesirable.

The word genocide was invented in 1943 by Polish jurist Raphael Lemkin (1900–1959). Lemkin also wrote Military Government in Europe, which was a preliminary version of his more fully developed publication Axis Rule in Occupied Europe (1944). In 1943 Lemkin was appointed consultant to the U.S. Board of Economic Warfare and Foreign Economic Administration and later became a special adviser on foreign affairs to the War Department, largely because of his expertise in international law.

The term is based on the Greek word genos, referring to race or tribe, and the Latin term cide, meaning murder. Lemkin created the term to refer to a new crime committed against group victims and involving, "a coordinated plan of different actions aiming at the destruction of essential foundations of the life of national groups, with the aim of annihilating the groups themselves" (1944).

Lemkin invented the term because he believed that the Nazi’s planned eradication of various groups represented an irreparable harm to global society, as well as a special challenge to existing conceptions of criminal law, which tended to focus on crimes committed against individuals.

The text of the UN Genocide Convention was completed in 1948, and in 1951 the Convention became a
Genocide

ated acts are distinct in nature, yet unified as strategies

ments: acts, intent, and victim group. The five enumer-

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION

The prohibition on genocide is now so widely

accepted that it has become a part of international cus-

tomy law so that it is understood to be binding on all

states, regardless of whether or not they have ratified the

Genocide Convention.

The legal definition of genocide is found in Article II

of the Convention. This definition is widely accepted and

has been reinforced by its repetition in relevant domestic

legislation and in the statutes of the International

Criminal Tribunal for Yugoslavia (ICTY), the

International Criminal Tribunal for Rwanda (ICTR), and

the International Criminal Court (ICC). Article II defines

the crime as follows:

In the present Convention, genocide means any

of the following acts committed with intent to

destroy, in whole or in part, a national, ethnic,

racial or religious group, as such:

(a) Killing members of the group;

(b) Causing serious bodily or mental harm to

members of the group;

(c) Deliberately inflicting on the group conditions

of life calculated to bring about its physical

destruction in whole or in part;

(d) Imposing measures intended to prevent births

within the group;

(e) Forcibly transferring children of the group to

another group. (OHCHR [1948] 1951)

In this way, genocide is composed of three key ele-

ments: acts, intent, and victim group. The five enumerated

acts are distinct in nature, yet unified as strategies

that can either destroy an existing group (killing, causing

serious harm, creating destructive conditions) or ruin the

possibility of the group’s continued existence (preventing

reproduction and forcibly removing children). The issue

of intent is complex, but is generally understood to limit

claims of genocide to those cases where political violence

is purposefully directed, either as an officially stated pol-

ic to destroy a group or as expressed through an analysis

of repressive strategies. The idea of a victim group defines

genocide as a unique crime in which individuals are tar-

geted for repression because of their membership in either

a national, ethnic, racial, or religious group.

Each element of the legal definition of genocide raises

complex questions, many of which run counter to domi-

nant moral and social understandings of the term. That is,

 genocide is widely understood to be a crime involving

mass murder and the idea of destroying “in whole or in

part” suggests some numerical threshold. So, while it

would trivialize the moral power of the concept to include

cases of hate crimes or small-scale racial killing, the

Genocide Convention allows a case of genocide to involve

few casualties, as with the forced transfer of children.

Similarly, the popular understanding of the crime assumes

that the mass killing of hundreds of thousands would con-

stitute genocide, yet the Convention’s definition only

covers acts committed against one or more of the four

protected groups and may not, for example, cover the bru-

tal destruction of political opponents (as in the Khmer

Rouge’s killing of 1.7 million in Cambodia in the 1970s).

Equally complex is the question of whether group status is

a function of perpetrators’ understandings of targeted vic-

tims (so that the Nazi’s vision of Jewish identity would

define the group) or whether the concept seeks to protect a

group defined by some inherent, objective, or actual

identity, a problem heightened where different groups

appear highly similar (as with Rwandan Hutus and Tutsis,

who speak the same language, practice the same religions,

and commonly intermarried).

In order to address these issues, scholars have

expanded the interpretation of the crime to cover many

instances of mass violence, or created new terms such as

autogenocide to deal with mass murder where perpetrators

and victims are of the same group, or democide to refer to

mass killing based on any justification. While these efforts

play an important role in evolving understandings of the

crime, the Genocide Convention’s definition remains the

central understanding of the concept.

Despite the widespread acceptance of genocide as a

crime, there were few twentieth-century attempts to pros-

ecute individuals. In fact, it was not until 1998 that the

first international prosecution and conviction for genocide

took place in the Jean-Paul Akayesu case at the ICTR. This

historic decision was followed by a number of additional

cases in the same court (Jean Kambanda, etc.), as well as

other important cases at the ICTY (Milan Kovacevic,

Radislav Krstic, Dusko Tadic, etc.), allowing for the evolu-

tion of a new jurisprudence of genocide. The decisions of

these ad hoc tribunals represented an important expansion
of the international legal commitment to prosecuting genocide. This commitment was further supported by the creation of the ICC in 2002, which provides a permanent body for prosecuting cases of genocide and other severe atrocities. Also in 1998, a Spanish judge brought genocide charges against former Chilean dictator General Augusto Pinochet in a domestic court for crimes committed in South America. This ushered in a new era of using the concept of universal jurisdiction as a means of prosecuting individuals accused of genocide in national courts in countries distinct from where the violations occurred.

The Genocide Convention was also created to prevent genocide, ideally by stopping potential genocides before they occur, or by taking action against severe violations before they reach a genocidal intensity. Yet, since the mid-twentieth century, the world has witnessed many atrocities often described as genocide. These include Cambodia (1975–1979), Rwanda (1994), and mass political violence in the former Yugoslavia (1992–1995) that brought the world a new, nonlegal term, ethnic cleansing. In addition, there have been formal claims of genocide associated with atrocities throughout Latin America in the 1970s and 1980s, especially the Guatemalan military regime’s attacks on indigenous people. And, there have been claims of genocide against the former Soviet Union for military actions in Afghanistan and elsewhere, as well as state policies such as the use of famine to kill seven to fifteen million Ukrainians. In Africa, there have been numerous genocide claims, most recently in the Sudan.

The case of Rwanda is especially chilling in that an estimated 800,000 people, generally Tutsis, were killed with machetes and small arms by a Hutu-dominated regime in 1994. Before the killing began, UN peacekeepers warned of an upcoming genocide and estimated that an international force of around five thousand could have prevented the violence. During the hundred-day killing, the international community refused to acknowledge that genocide was taking place, in part to avoid the legal responsibility to act. Later, most nations recognized these killings as an example of genocide, but by then the murderous regime had been removed from power by a Rwandan rebel army.

In many respects, genocide defines the twentieth century, representing a harsh warning of the destructive capacity of modernity as well as the open promise of the benefits of international cooperation. Genocide is one of the central, foundational ideas within human rights discourse, which represents the first universal structuring discourse of an emerging global order. Genocide was defined formally through global commitment toward its punishment and prevention. In this sense, the term is almost iconic in its representation of the complexity of modernity, defining both the worst and best of human society, a word that names acts of unforgivable brutality while offering the promise of a world where such acts cannot be tolerated and can only exist within the imaginary, banished from the real through concerted, coordinated, international action.

Daniel Rothenberg

Genomics

The term genomics was coined in 1987 by Victor A. McKusick and Frank H. Ruddle as the title for a new journal of that name. McKusick and Ruddle derived it from...
Genome, a concept that had been circulating in biology since the early 1920s. The roots of genome are the Greek genos (class, kind, race) and the suffix -ome (as used in rhizome and chromosome.). Genome is defined as the entire sequence of DNA found in the nucleus of every cell.

In the 1980s and 1990s, genomics primarily referred to large-scale projects to map the genes and sequence the DNA of organisms. As it turned out, a bacteriophage called phi-x174 was the first organism whose complete DNA sequence was revealed. The sequencing of its 5,375 nucleotides was accomplished in 1977 by Frederick Sanger and his colleagues at the University of Cambridge. In the ensuing two decades, a series of further viral genome-sequencing projects were undertaken. In July 1995 Robert David Fleischmann reported the completion of the sequencing of the first genome of a nonviral organism (H. influenzae).

Encouraged by the chancellor of the University of California, Santa Cruz, Robert Sinsheimer, and the U.S. Office of Health and Environmental Research, biologists began in the mid-1980s to evaluate the possibility of mapping the genes and sequencing the DNA of the human genome. As part of its mission to assess the health effects of radiation, the U.S. Department of Energy established in 1987 three human genome research centers at Los Alamos, New Mexico; Livermore, California; and the Lawrence Berkeley National Laboratory in Berkeley, California. The initiative to first map and then sequence the complete human genome was formally launched in 1990 as a joint program of the Department of Energy and the National Institutes of Health. In France, the Centre d’Étude du Polymorphisme Humain conducted a successful gene-mapping project funded by the Muscular Dystrophy Association. In the United Kingdom, the Wellcome Trust supported human genome research. Germany and Japan soon joined the international efforts in what was called a “race” to map the genes and sequence the 3.1 billion base pairs of the human genome.

In the wake of a successful initial mapping of the human genome, the Human Genome Organization decided by the mid-1990s to decode the DNA of model organisms before sequencing the human genome. In 1997 the complete DNA sequence of the yeast genome was published; a year later the ninety-seven million base pairs of the worm C. elegans followed; in early 2000 an advanced draft of the genome of the fruit fly Drosophila was announced.

Using different approaches, the Human Genome Sequencing Consortium and a team led by Craig Venter at Celera Genomics separately published in February 2001 their preliminary findings, estimating the number of genes in the human genome at 30,000 to 40,000. A later reanalysis reduced the number to approximately 20,000 to 25,000. The completion of the project in April 2003 has led to the identification of millions of sites on the genome where individuals differ.

The challenges in completing gene-mapping and DNA-sequencing projects were primarily technical, organizational, and financial rather than scientific. The problem scientists face today is how to use genomic information to gain biological understanding. Accordingly, genomics has increasingly given way to postgenomic studies focusing on the functions of genes and the complex interactions between cells, systems of cells, multicellular organisms, populations of organisms, and their environment. The three terms functional genomics (the study of genetic function), proteomics (the study of the proteins expressed by a genome), and transcriptomics (the study of RNA transcripts) indicate that the epistemic status of the genome has shifted from an object of analysis to a tool of research. In the emerging world of postgenomics, sequences are used as giant reference tools.

The social relevance of genomics lies primarily in the agricultural and biomedical utilization of genetic information. Knowledge gained from genetic and genomic research has enabled biomedicine to envision the organism at a molecular scale. New diagnostic tests based on a molecular understanding of life reveal susceptibility to a broadening range of diseases. The concept of genetic risk factors has led to a redrawing of the line between the normal and the pathological. Additionally, various patient groups have formed around specific diseases, inflecting new styles of collective thought, action, and passion that entail a redefinition of both the biological and the social. As a consequence, a new moral landscape has emerged that contrasts with the ethical discourse of the public sphere.

The challenge of contemporary molecular biology is to proceed from the generation of genomic information to the assessment of hypothetical propositions in experimental settings. For social scientists, it will be of paramount importance to continue observing and analyzing the unexpected emergence of objects and the unpredictable reconfiguration of forms as they assemble into an ever-shifting understanding of life.

GENTILITY

For over five centuries, English-speaking societies have given the terms genteel and gentility a series of definitions and connotations. To varying degrees in different historical contexts, believers in gentility have made honorable family roots, refined manners, and tasteful elegance signs that distinguish those in the genteel ranks from decadent aristocrats, showy upstarts, vulgar tradesmen, and ordinary hardworking people. Individuals have maintained their elite status through an artful pretense that masks both their true feelings and the effort they exert to make their genteel appearance seem “natural.” Throughout the centuries, there has been a tendency for many who were looked down on as “provincial,” “frontier,” “colonial,” “nouveau riche,” or simply “common” to seek upward mobility and new privileges by emulating their “betters,” often with the guidance of prescriptive literature. Even in periods when gentility no longer required upper-class ancestors, it has never lived comfortably with egalitarian democracy.

THE ROOTS OF GENTILITY

Etymologists have traced the roots of the word gentility to Latin, then to French, and finally to gentilete in Middle English. In the thirteenth century, English speakers used the word gentle to describe the landed gentry, and by the sixteenth century, gentle had evolved into genteel. During the Renaissance, some Europeans merged the new humanistic respect for learning with the medieval admiration of military glory to create a new class of gentleman who were neither nobles nor common folk. They displayed their status, in part, through their right to “bear arms,” meaning the right to display both a sword and a coat of arms.

In the eighteenth century, English and American pamphlets used genteel, in the sense of “being appropriate for gentlemen,” as a modifier in their titles for a wide variety of terms and activities, including “genteel places of amusement,” “genteel toasts, sentiments, and hobnobs,” “genteel feats of action,” “genteel designs for parsonages and farm houses,” and “genteel ingenious conversation.” By the time of the American Revolution, anyone in the broader class of gentlemen—wealthy merchants and planters, court and government officials, some members of the clergy, and other professionals—needed to live by the genteel code, while those in the lower classes could be shunned if they tried to pass themselves off as true gentlemen. Some twentieth-century historians, such as Howard Mumford Jones, Louis B. Wright, and Thomas Wertembaker, have depicted gentility in eighteenth-century America as a positive force, while others, including Carl and Jessica Bridenbaugh, Jack P. Greene, and Kenneth Lockridge, have asserted that it was an obstacle to the development of a more authentically American culture.

GENTILITY, INDUSTRY, AND COLONIALISM

As gentility continued to evolve in the nineteenth century, definitions for gentleman in the Encyclopaedia Britannica changed from “one, who without any title, bears a coat of arms, or whose ancestors have been freemen” in 1815 to “all above the rank of yeoman” with “that self-respect and intellectual refinement which manifest themselves in unrestrained yet delicate manners” in 1856. In 1891, America’s Century Dictionary added the possibility that gentlemen might be “fastidious,” demonstrating excessive “pride in refinement and family position.” These variations on the basic theme sometimes reflected political tensions, as when the genteel supporters of John Quincy Adams shuddered at the news of rough supporters of Jacksonian democracy celebrating in the White House after the inauguration of their hero, Andrew Jackson. In the decades before the U.S. Civil War, southern planters developed an image of genteel slaveownership characterized by benevolent paternalism, partly as a counter to abolitionist challenges to their moral character.

As industrial capitalism allowed men who had made quick fortunes to gain more power than established gentlemen, a group of authors, including Ralph Waldo Emerson, James Russell Lowell, Oliver Wendell Holmes, Henry Adams, Henry James, and Charles Eliot Norton, sought to cultivate an elite esthetic sense of culture. George Santayana labeled their writings the “genteel tradition.” In the twentieth century, Van Wyck Brooks and Vernon Parrington were among the scholars who criticized the genteel tradition for having inhibited realism in American literature and having been indifferent to the needs of ordinary people.

The spread of colonialism stimulated an imperialistic gentility to distinguish colonial authorities from the “less civilized” natives. British consular officials, for example, dressed in formal dinner attire while dining by a tent in an African jungle. Some individuals from the colonized societies emulated such behavior to gain favors from officials. Virginia tobacco planters, for example, built homes according to the standards of the English gentry, and educated natives of India learned to play cricket. Those with dark skin could not, however, expect to gain total approval from their rulers. White supremacists took it for granted that the basic nature of “people of color” was too dishonorable for them to be capable of refined taste and manners. This made those categorized in this demeaning fashion even more determined to display genteel qualities whenever they could afford to do so. Nevertheless, in the Jim Crow South, white southerners were extremely hostile to public genteel behavior by African Americans. Some black families decided not to paint their homes, lest the
local white community discover that they possessed a refined parlor, complete with a piano.

GENTILITY AND THE RISE OF THE MIDDLE CLASS
Even though gentility can never be truly democratic, the rise of the middle classes in the nineteenth century led to an increase in individuals seeking a genteel identity. While those who were born into elite status claimed to notice a marked difference between a person who was “acting like” a lady or gentleman and someone who actually was one, the popularity of advice books indicates that not everyone agreed with such rigid exclusivity. Emily Thornwell, for example, published an especially popular manual in 1856 titled The Lady’s Guide to Perfect Gentility, in Manners, Dress, and Conversation, in the Family, in Company, at the Piano Forte, the Table, in the Street, and in Gentlemen’s Society. While explaining what forks to use when, these etiquette advisers also encouraged their readers to buy everything needed to furnish a genteel home, creating what the historian Richard Bushman has labeled “vernacular gentility.” After World War I, according to the historian Stow Persons, distinguishing between gentlemen and common men was no longer socially useful.

GENTILITY, GENDER, AND WORK
Whether in the sixteenth century or the twentieth, certain assumptions have been standard elements of gentility. A firm opposition to any ambiguity in gender roles has led to the dismissal of anyone whose behavior was not up to the standards of genteel femininity and masculinity. In the nineteenth century, some men focused on countering assumptions that refined style might be effeminate by calling for a more “manly” gentry. Courtship rituals reflected an idealization of the medieval code of chivalry, which gave demure belles the most public power they would have in their lives, as they charmed suitors before choosing one to be their husband.

A genteel work ethic has encouraged gentlemen to focus almost exclusively on elite leisure activities, whether studying Greek classics or betting on horse races, rather than on practical survival strategies and tactics. In the fourteenth century, John Ball, the leader of a peasants’ revolt against privileges for elites who did no work, summarized this assumption in a couplet referring to the story of Adam and Even in Genesis that lived on as a nursery rhyme: “When Adam delved and Eve span, / Who was then the Gentleman?” (Bartlett, 871). A prejudice against “tradesmen” lasted into the twentieth century on the European continent and inspired a number of New England businessmen in the nineteenth century to seek to become “gentleman farmers” once their fortunes were secure. For much of the twentieth century, upper-class male college students were proud of earning a “gentleman’s C.”

The genteel work ethic for ladies has required socializing frequently enough to assure their families’ elite connections while also avoiding the company of anyone without the proper genteel credentials. Women made time for visiting by engaging in a genteel domesticity that involved overseeing servants rather than undertaking any menial chores themselves. Elite mothers trained their children in genteel behavior, including the art of polite conversation, but servants did much of the childcare. For ladies, ornamental sewing and occasional baking, as well as singing to entertain guests, needed to be obviously optional amateur activities that would showcase a lady’s “accomplishments” for the pleasure of others.

When gentlemen who refused to pay attention to business matters lost some of their family’s fortune, they could depend on their peers to ascribe their genteel poverty to historical victimization rather than to individual failings. Nevertheless, those without much financial wealth sought to heighten the value of the cultural capital of genteel behavior relative to economic capital, and to avoid social contact with anyone whose “new wealth” made their social status questionable (unless they were quietly seeking a “blood and money marriage” for one of their children). “Shabby gentility” first became a popular topic in English fiction in the eighteenth century. In his novel The Old Curiosity Shop (1840-1841), Charles Dickens described “poor streets where faded gentility essayed … to make its last feeble stand” (Dickens, 115).

In recent decades, the status of celebrity has overtaken that of gentility, allowing rock stars to be knighted by the Queen of England for their contributions to the British economy. But the terms genteel and gentility are not obsolete. At least one American fraternity still instructs its members that each should, “through his gentility,” seek to follow the ideals of chivalry, including good manners and respect for women. From another perspective, the newspaper columnist Frank Fitzpatrick, on July 14, 2006, published an article condemning the owners of the Philadelphia Phillies baseball team for their inability to understand the anger of the “real Phillies fans” because their anachronistic “genteel worldview” still considered sports to be “an aristocratic club.” Whether future generations will be equally contemptuous of the concept of gentility, or develop a new version to suit their particular social ambitions, remains to be seen.

GENTRIFICATION

Gentrification marks the revival of urban areas by a set of interrelated demographic, economic, and spatial changes: new investment in housing, an influx of highly educated, culturally aware residents and consumers, and the shift from an industrial to a service economy with jobs in the center city for professionals and artists. First observed in London during the 1950s but gradually spreading through North American, Australian, and European cities, the movement of middle-class households into old working-class neighborhoods took most observers by surprise because it contradicts the much greater flow of people and capital outward to new suburbs and the presumed decline of urban life. But gentrifiers reject the social class and ethnic homogeneity of most suburban housing developments. They are attracted to the social diversity of city life, the aesthetic qualities of old buildings, and the cultural vitality of the streets. The low cost of housing in centrally located but derelict and often crime-ridden neighborhoods also appeals to them. Although they take a risk by investing in and moving to these areas, they benefit from the cultural amenities they help to develop and from steadily rising property values.

Because gentrification raises housing prices and brings a different sort of commercial culture to older neighborhoods, gentrifiers are nearly always suspected of displacing low-income residents. In many cities where high-level business services and high-tech sectors have expanded and redevelopment plans focus on the downtown, rising rents and sale prices do increase the housing burden for a large part of the urban population. Higher rents also threaten the cheap stores and local services that cater to low-income residents; landlords prefer to end their leases and replace them with boutiques, cafés, and bars that will draw middle-class customers. The types of services these consumers want—and the atmosphere they prefer—are often seen as alien by their poorer, older, and less educated neighbors and tend to make these earlier residents feel culturally as well as economically displaced. But precise data on displacement are difficult to find, and some local residents may choose to move either to a cheaper location in the same area or to a different place entirely. Older home owners in particular may take the opportunity to move away if their children do not want to live in their house and they can make a large profit by selling it.

City governments and the media downplay displacement in order to encourage new investment and develop attractions for tourists and residents. Along with new residents, they describe the existing area as a “wilderness” and the gentrifiers as “pioneers.” These metaphors thinly veil a continuous pressure to upgrade the city by replacing low-income groups, who often depend on public services, with more affluent taxpayers and to replace low-rent, low-status manufacturers with residential tenants. Because gentrification in the form of loft living became widespread during the 1970s due to the residential conversion of manufacturing space, it is difficult to say whether gentrifiers contribute to or simply follow industrial dislocations and factory shutdowns. By the same token, gentrifiers often move into neighborhoods that have already lost residents because of property owners’ disinvestment and abandonment as well as a decline in public services.

The media actively promote the sense of style that gentrification evokes. While loft living is associated with open spaces, high ceilings, and stark modern decor and the rehabilitation of town houses with small rooms and original, Victorian architectural detail, each suggests a cultural transformation of the inner city from physical dilapidation and social disadvantage to an attractive consumers’ zone. Because of new residents’ higher salaries, dual income households, and cultural capital, gentrified areas of the city soon sprout ambitious restaurants, art galleries,
performance spaces, and unusual designer boutiques. The high degree of self-employment among gentrifiers who work in cultural fields provides them with both a daytime and a nighttime clientele. Moreover new shops and cafés are featured in going-out guides and style magazines, bringing more visitors from other areas of the city as well as from suburbs and overseas. In this way the lifestyle elements of gentrification repair damage to the city's image from post–World War II disinvestment and the flight of many middle-class residents. Together with housing prices, gentrifiers' cultural tastes act as agents of change, reducing the number of working-class, middle-income, and “minority” neighborhoods.

Although gentrification is viewed as a market-based alternative to state-sponsored urban renewal, it cannot succeed without active state intervention. Local government condones years of disinvestment and capital flight from older areas, creating a “rent gap” between the profit to be gained at current housing prices and the likely profit from reinvestment in the future. Zoning laws prohibit the expansion of manufacturing, encourage historic preservation, and create special cultural districts. Vigilant policing makes gentrified neighborhoods safer. In some cases elected officials, business leaders, and old social elites plan the gentrification of a center city neighborhood to stall further decline of property values.

If it raises a neighborhood’s profile, gentrification may lead to rezoning for new construction, and successive waves of gentrification replace middle-class home buyers with even richer residents. Over time the character of these neighborhoods changes, although not enough to eliminate social inequality in the city as a whole.

GEOGRAPHY
Geography is the study of the field of knowledge relating to the temporal and spatial dimensions of the processes that shape the Earth's surface. Implicit within geography as a discipline is an emphasis on ways that diverse systems interact over time, producing particular landscapes in particular places. Geography is distinct from other disciplines (such as spatial economics and geology) in that it emphasizes the dual dimensions of time and space as causal, and because it highlights the importance of feedback between these different dimensions. A landscape can be understood as a place-specific configuration of interacting systems (at any scale), whose features influence the geographical processes operating in that particular case (this interaction produces feedback). The term landscape is often used to describe systems in which natural processes predominate, while place is used to describe systems dominated by human processes, though this distinction is not absolute. Indeed, in human geography the term landscape is used by many to describe anthropogenic systems, giving the effect that the phenomenon is distinct from the humans inhabiting it.

There are several ways of subdividing the discipline of geography. A common distinction is often made between physical geography as an environmental science and human geography as a social science. Human geography can further be divided according to the topic of study, creating subfields such as urban, political, economic, social, historical or cultural geography. More abstract dividing lines can also be drawn on the basis of methodologies, so that a distinction can be made between quantitative approaches, which have much in common with orthodox economics and cartography, and qualitative approaches, which can be similar to sociology, planning anthropology, and political science. Since the quantitative revolution of the 1960s, geographers have also distinguished themselves according to their epistemological perspectives on the nature of reality and the possibility of individuals adequately understanding and describing that reality.

THE EMERGENCE OF THE DISCIPLINE OF GEOGRAPHY
Geography as a discipline emerged in Germany in the eighteenth century in the context of attempts associated with Alexander von Humboldt at the University of Berlin to systematically harness the benefits that universities provided to society by creating applied disciplines linked to social needs. The ancient civilizations were interested in geographical topics such as cartography and cultural geography in the context of operating their military and trading empires. These proto-geographical ways of thinking were primarily concerned with describing the form of the earth, often in an attempt to better control a particular activity rather than produce pure knowledge of geographical systems. It is important to note that these applied uses of geography have created a continual stream of wealthy patrons willing to fund exploration to producing spatial
knowledges, which have often served those patrons’ own power interests.

According to Richard Hartshorne’s *The Nature of Geography*, geography as a discipline emerged from a growing body of practical studies after 1500, but it was from 1750 onward that serious attempts were made to establish the two preconditions for a discipline, namely a distinctive subject area and a rigorous analytic methodology. The renowned philosopher Immanuel Kant (1724–1804) saw a close and necessary connection between understanding the nature of the world, and developing a more general (abstract) philosophical method. Hartshorne relates that Kant’s physical geography course became a staple of his philosophy curriculum, being repeated forty-eight times from 1756 to 1796 at the University of Königsberg (now Kaliningrad). Kant developed the idea of *Länderkunde*, of studying particular distinctive regions in detail to understand their emergence. This approach was extended throughout the early nineteenth century by other early geographers, such as Von Humboldt and Carl Ritter, who viewed the human and physical elements of places as inseparable elements of a unitary whole (*die Ganzheit*), of a region or landscape. Humboldt, in particular, tried to ensure that the focus of study was on classes of places (classified, perhaps by climate, geology, social form) rather than classes of objects (such as species).

Humboldt’s efforts to create a science of geography were ultimately responsible for a postmortem split between *systematic* geographers, studying physical processes and landforms, and *regional* geographers, studying societies in particular climatic and geological regions. This cleavage deepened in the course of the nineteenth century, as geographers sought to specialize and establish themselves in the many new and growing universities. However, this tension was never fully resolved, and as geography began to institutionalize, the newly formed learned societies reflected both halves of the discipline: systematic (physical) geography and regional (human) geography.

**GEOGRAPHY FROM 1900 ONWARD**

The story of geography since 1900 is one of an established discipline advancing rapidly, driven by and responding to the huge social and physical changes accompanying the rise of industrial society, alongside increasing technological opportunities for new forms of research and knowledge production. During the twentieth century, a number of currents of thinking emerged that were driven by ideological considerations. Environmental determinism, for example, provided an intellectual underpinning for the imperialistic “Race for Africa” in the late nineteenth century by arguing that climatic considerations meant that African civilizations were incapable of developing stable social institutions. Likewise, desire for *Lebensraum* (living space) of the National Socialists in Germany drew on geopolitical thinking that originated with the English geographer Halford Mackinder’s concept of geopolitics to rationalize these ideological desires within the school of *Geopolitik*. The collapse of both underpinning ideologies carried a collateral cost for their parent disciplines as a whole. It was this tendency for supposedly neutral geographical analyses to favor particular powerful groups that was the stimulus behind the radical turn in human geography that emerged in the 1970s.

In parallel with these changes, two important geographical movements emerged to reshape the discipline in the period from 1900 to 1970. The first of these was the systematization of regional (human) geography, which attempted to move beyond ideographic descriptions of societal phenomenon in particular places to more analytic expressions of places in terms of underlying processes. However, it is important to stress that national geographies remained highly distinctive at this time, and these new regional geographies reflected these national distinctions. British regional geography, particularly in the works of Henry Daysh, H. C. Darby, and Hilda Ormsby reflected national traditions of empiricism and pragmatism while emphasizing the importance of historical development. French writers, led by Paul Vidal de la Blache, produced the *Annales* school, named after its journal, which developed notions of “environmental possibilism,” in which social configurations (*genres de vie*) were influenced both by physical environment and social and political decisions. German writers, notably Walter Christaller and Alfred Weber, used mathematical modeling to understand the spatial allocation of human activity such as settlements and industry. This represented a more analytic attempt to understand human activity. Although these diverse national approaches differed in the extent to which they emphasized theory over practical observation, they clearly all represented an attempt to systematize the production of geographical knowledge.

This consensus emphasizing systematization enabled the second great geographical movement of the twentieth century, the quantitative revolution. Early systematic approaches, inspired by the natural sciences, suggested that everything in nature was knowable, given sufficient data and analytic capacity. The increasing “scientization” of society in general, and the rise of computer power after 1947 in particular, seemed to bring this dream of total geographical knowledge within reach. The basis for quantitative geography lay in creating mathematical spatial models to account for the distribution and evolution of particular phenomenon over space. The quantitative revolution became associated in the United States with the Regional Science movement, pioneered by Walter Isard,
then a professor at University of Pennsylvania, and his supporters. By infusing geography with mathematical and statistical tools, Regional Science superficially avoided the charges of selectivity and ideological determination that afflicted more ideographic geographical approaches. In part, the popularity of these quantitative approaches derived from the apparent certainty of knowledge thereby produced, which gave policymakers a robust evidence base for making decisions about land use and economic planning.

However, quantitative approaches often suffered from failing to adequately capture the independent variables, the factors responsible for causing particular phenomena. Quantitative practitioners were making assumptions and using convenient proxy variables rather than capturing complex social and cultural phenomena. The increasing urban segregation and deprivation in the 1960s and 1970s in western Europe and America provided a direct challenge to quantitative geography’s capacity to explain away the emergence of ghettos, dereliction, and, frequently, rioting. Faced with the inability to measure causal variables, a number of geographers instead began to form theories to try to understand how large-scale “social structures” created micro- and meso-scale problems.

Arguably the most celebrated of these geographers is David Harvey, whose empiricist manifesto *Explanation in Geography* (1969) was supplanted by a Marxian commitment to understanding spatial process in terms of class struggle, beginning with his 1973 treatise *Social Justice and the City*. Harvey exemplified a “radical geography” in which class theory allowed hidden power relationships to be exposed and unexpected causalities to be identified. This radical approach fitted neatly with, and has since become associated with, a more general postmodern or relativistic turn in the social sciences. Harvey’s neo-Marxian writings reached what many regard as an apex of radical critiques of globalization and neoliberalism.

Radical geography subsequently proceeded through a number of further “turns,” which have critiqued their predecessors in an attempt to better understand what drives the development of human societies. The cultural turn emphasized the importance of noneconomic interaction and transactions; the institutional turn noted the importance of durable organizations and social norms; and the relational turn highlighted the fact that people are influenced by what is close to them, and that proximity is not just physical but can be organizational, cultural, or virtual in nature. These turns were all led by movements comprising both established geographers who recanted or redacted their established positions and emerging geographers who became a new generation of intellectual leaders for geography. The cultural turn was signaled in 1989 by the parallel publications of David Harvey’s *The Condition of Postmodernity* and Edward Soja’s *Postmodern Geographies*. Both books asked fundamental questions about the economic focus of much Marxian geography, and they laid the foundations for more reflexive understandings of economic activity. These “turns” have been contested by other geographers, who have expressed concerns that the intellectual efforts involved in reflexivity have detached them from geographers’ central task of understanding real places and spaces.

At the same time, quantitative approaches have continued to develop. Geographical information systems (GISs) are massive computer databases into which huge quantities of locational data is entered, allowing the performance of additional “fieldwork” capable of identifying regularities that are not immediately obvious. Although they are academic tools, much of the investment in them came from customers seeking to make sense of unknown and uncertain environments, notably the military and oil exploration companies. The continual investments these tools produce have generated a wide range of applications, and GISs are now commonplace across the spatial sciences beyond geography.

Quantitative geographers have also used novel mathematical techniques and increasing computing power to address “traditional” geographical problems of understanding how spatial distribution and irregularities in distribution cause geographical processes to behave in different ways in different places. These approaches are exemplified by the geographically weighted regression (GWR) technique. There has also been an increasing dialogue between physical and human geographers trying to deal with the complex environmental problems that have emerged with the increasing industrialization of society. This neatly emphasizes the ongoing indivisibility of the “natural” and the “anthropogenic” elements of geographical systems, as well as the mutual understanding necessary to understand the development of spatial systems.

GERONTOLOGY

The scientific study of the biological, psychological, and sociological phenomena associated with age and aging, gerontology had its origins in the study of longevity from Francis Bacon (1561–1626) onward. While Jean-Martin Charcot (1825–1893) had explored the relationship between old age and illness, the term gerontology was introduced by Élie Metchnikoff (1845–1916), who developed theories of aging based on his work in medicine and biology. Social science perspectives on aging did not emerge until later, when the economic consequences of aging were recognized. Professional associations were created to support research on aging, such as the Gerontological Society of America (1945) and the International Association of Gerontology (1948). In the 1930s the Josiah Macy Jr. Foundation in New York, under the directorship of Ludwig Kast, ran a series of conferences on aging exploring the relationship between degenerative disease and aging. The Foundation encouraged E. V. Cowdry, professor of cytology at Washington University, to organize a book that would explore not only the biomedical aspects of aging but also the psychological, sociological, and environmental aspects. These activities resulted in the Club for Research on Aging, which promoted the study of aging as an aspect of public health. Major figures in the development of the social and psychological study of aging included, in the United States, Matilda White Riley (1911–2004), and in the United Kingdom, Peter Laslett (1915–2001). Riley and her colleagues developed the “aging and society paradigm” in her Aging and Society (1968–1972), which examines the interaction between a cohort flow of population and social change, and explains age as an aspect of the social structure. Laslett, the author of The World We Have Lost (1965), challenged many conventional, but dubious assumptions in demography and gerontology, such as the idea that the nuclear family is a modern development. He was a founder of the influential Cambridge Group for the History of Population and Social Structure, which pioneered the methodology of using local records in the historical study of population.

Gerontology has become an increasingly important discipline as the governments of the developed world face up to the problem of aging populations. The causes of population aging are either a rising life expectancy or declining fertility, or both. Increasing longevity raises the average age of the population; a decline in fertility increases the average age of the population by changing the balance between the young and old. In the modern world, declining fertility—in precise terms the actual number of live births per thousand women of reproductive age—is the most significant cause of population aging. In terms of the world population, in the year 2000 approximately 30 percent were under the age of fourteen years, but this is expected to fall to around 20 percent by 2050. In the developed world, the median age of the population rose from 29 in 1950 to 37.3 in 2000, and it is predicted to rise to 45.5 by 2050. For the world as a whole, the figure was 23.9 in 1950, 26.8 in 2000, and it is predicted to be 37.8 for 2050. One of the fastest-aging populations is modern Japan; in 1950 there were 9.3 people under the age of 20 for every person over 65 in Japan, but by 2002 this ratio was anticipated to be 0.59 people under 20 for every person over 65 years. Worldwide, there are important regional variations. If we define an aging population as one in which at least 10 percent are over 60, then most of sub-Saharan Africa will only see the development of aging populations after 2040, but North Africa will have them before 2030. Most of the Latin American and Caribbean countries will have aging populations after 2010. Many Asian countries, such as China, Singapore, and South Korea, already do.

The United States and Northern Europe face an acute problem of rapid aging. In the United States, the proportion of the population over sixty-five years of age is expected to increase from 12.4 percent in 2000 to 19.6 percent in 2030. In absolute terms, this means an increase from 35 million over sixty-five in 2000 to 71 million in 2030. In Europe the number of people over sixty-five years will increase from 12.4 percent in 2000 to 19.6 percent in 2030.
The aging of the world population is an aspect of an ongoing demographic transition—a switch from high fertility and high mortality rates to low fertility and delayed mortality. This transition also produces an epidemiological transition—a switch from infectious diseases in childhood and acute illness, to chronic disease and degenerative illness. The principal causes of death in the developed world are cardiovascular disease, cancer, respiratory disease, and injuries.

These demographic changes have major implications for health care, the labor force, welfare, insurance, and pensions. In the United States 80 percent of people over sixty-five years have at least one chronic disease and 50 percent have two. Diabetes now affects one in five Americans. The incidence of Alzheimer's disease in the United States doubles every five years after the age of sixty-five. The economic consequences of an aging population are various and significant. There will be major increases in health care, nursing care, and retirement home costs. As the ratio of working to retired persons increases, there will be a decline in taxation and an erosion of funds for public expenditure. There is already a significant pension crisis in the United States and the United Kingdom, where the combination of compulsory retirement and increasing life expectancy means that people do not have sufficient savings for old age. The problem is a major policy issue because labor force participation of people over sixty-five years has declined by more than 40 percent worldwide. In the United States, the growth rate of the working-age population is projected to decline from its current level of 1 percent per year to half a percent by 2030.

Life expectancy has increased significantly in the developed world. More people are surviving into old age, and once they achieve old age, they tend to live longer. Over the next half century, global life expectancy at age 60 will increase from 18.8 years in 2000–2005 to 22.2 years in 2045–2050, from 15.3 to 18.2 years at age 65, and from 7.2 to 8.8 years at age 80. In over thirty countries female life expectancy at birth already exceeds 80 years. Can life expectancy increase indefinitely?

Contemporary gerontology as a field of research is changing rapidly under the impact of advances in the biological sciences. In conventional gerontology, living a long life had meant in practical terms living a full life, according to some agreed upon set of cultural and social criteria, and achieving the average expectation of longevity according to gender and social class. More recently however, there has been considerable speculation as to whether medical science can reverse the aging process. Between the 1960s and 1980s, biologists such as Leonard Hayflick (1982) argued that normal cells had what was known as a replicative senescence, that is, normal tissues can only divide a finite number of times before entering a stage of inevitable quiescence. Cells were observed in vitro in a process of natural senescence, but eventually experiments in vivo established an important and far-reaching distinction between normal and pathological cells in terms of their cellular division. It was paradoxical that pathological cells appeared to have no such necessary limitation on replication, and therefore a process of immortalization was the defining feature of a pathological cell line. Biologists concluded that finite division at the cellular level meant that the aging of whole organisms was an inevitable process. These scientific findings supported the view, shared by most religious traditions, that human life had a predetermined limit, and that it was only through pathological developments that some cells might outsurvive the otherwise inescapable senescence of cellular life. Aging was regarded as both natural and normal.

This traditional conception of aging was eventually overturned by the discovery that human embryonic cells were capable of continuous division in laboratory conditions, where they showed no sign of any inevitable “replicative crisis” or natural limitation. Certain non-pathological cells (or stem cells) were capable of indefinite division, and these new developments in the conceptualization of cellular life have consequently challenged existing scientific assumptions about the distinctions between the normal and the pathological. Stem-cell research is beginning to redefine the human body in terms of renewable tissue, and suggests that the limits of biological growth are not immutable or inflexible. The human body has a surplus of stem cells capable of survival beyond the death of the organism. With these developments in micro-bio-gerontology, the capacity of regenerative medicine to expand the limits of life becomes a plausible prospect of medicine, creating new economic opportunities in the application of life sciences.

The controversies that surround modern gerontology are primarily to do with population aging, resource allocation, and equality. First, can longevity be increased almost indefinitely? Secondly, will significant increases in life expectancy severely increase the inequality in the distribution of resources worldwide? Finally, can intergenerational justice be maintained?

In contemporary debates about the legitimacy of the life-extension project, faith-oriented beliefs and moral justifications are prominent. It is clearly the aspiration of furthering biomedical science that is the most common supporting argument in the literature. In general, scientific curiosity and potential health-enhancing discoveries are cited as justifications for life-extension research. The ethical principle of beneficence is also included, because the research, it is argued, can help to decelerate the aging process and diminish the onset of chronic illness. Such a
view emerges from a conception of aging as a condition to be cured (that is, as a disease), and it assumes that health and life extension will necessarily evolve together. In these debates on life extension, Gregory Stock, director of the program on Medicine, Technology, and Society at University of California, Los Angeles (UCLA) School of Public Health, argues that we should not accept the natural life span as a fixed state of affairs, because prolonged health is a general good. Because the technological advancements in anti-aging intend to provide more youthfulness to aging people, he contends that life extension is valuable both to individuals and for societies. Similar sentiments are reflected in the posthumanist perspective, which strongly advocates the overcoming of biological limitations through technological progress. One public figure promoting life extension in England is the editor in chief of Rejuvenation Research, Aubrey de Grey at the University of Cambridge, who has vigorously supported the life-extension project.

The arguments against life extension are that, given a scarcity of resources, it will greatly contribute to the depletion of natural resources and significantly increase environmental degradation. It will increase inequality between the Southern Hemisphere and the affluent Northern Hemisphere. It will have an adverse effect on intergenerational justice by further concentrating wealth in the hands of the elderly rich. Finally, it raises important issues about the psychological and spiritual distress that the elderly but disabled cohort of survivors would confront. The prospect of “living forever” would only be tolerable if medical science could guarantee a reasonable level of mobility and well-being (such as freedom from chronic disease). There would also be the prospect of intergenerational conflict, for example in the form of ageism.

The term ageism was first employed by Robert N. Butler, then director of the American Institute of Aging, in 1968. Referring to negative stereotypes of elderly individuals that classify them as senile, dependent, or conservative in their attitudes, ageism has become an important political issue. Against the background of the rapid aging of populations, new ageism refers to intergenerational conflicts of interests where the elderly are criticized for being parasitic on society, that is for being “takers” rather than “givers.” Some aspects of ageism can be overcome by making more accurate information about aging available, especially to young people. Another change would be to remove a fixed or compulsory retirement age, thereby allowing fit and able elderly to continue in employment. These strategies will come up against the fact that, given high unemployment, housing shortages, and other scarcities, there will be an inevitable conflict of interests between age groups. There are few convincing social policies to resolve the pension crisis, the impact on health care, and the erosion of the tax base that are outcomes of population aging.

This pessimistic conclusion can be challenged by arguing that technological improvements will continue to increase the productivity of those who remain at work, and that flexible retirement regulations will allow people to remain employed on a voluntary basis past sixty-five. We cannot assume that the values and attitudes of old people in the past will be characteristic of future generations. The postwar Baby Boomers who are now close to retirement are socially and culturally very different from their parents and grandparents. The social character of aging and the cultures of the elderly will continue to change and evolve over time, thereby making pessimistic extrapolations from past generations unreliable, and often prejudicial.

GERRYMANDERING

The term gerrymander typically refers to the creation of electoral districts that have bizarre shapes in order to condition the outcome of an election. In “Considering the Gerrymander” (1977), Leroy C. Hardy recounts that the term gerrymander was coined after the Jeffersonian-controlled legislature of Massachusetts drew contorted senatorial districts in order to ensure the defeat of Federalist candidates in 1812. One particular district located north...
of Boston was so contorted that it was said to look like the mythical salamander. Since this all took place during Elbridge Gerry's (1744–1814) term as governor, the district was christened a “Gerrymander,” and the term has stuck ever since.

Bizarre district shape is but one manifestation of the real evil of gerrymandering: the conscious attempt by someone to organize voters in a manner will result in the over- or underrepresentation of a particular group or political party. This can be accomplished using very unremarkable district boundaries. In addition, an electoral system can be gerrymandered by other means, such as unfairly altering the rules by which votes are counted and translated into electoral seats or changing the laws governing the qualification of candidates and political parties to appear on ballots.

Gerrymandering takes on benign as well as evil forms. Perhaps the most egregious example of modern gerrymandering in the United States took place in Alabama in 1958. The black population of the city of Tuskegee was about to become a majority of the electorate. White residents petitioned the state legislature to redraw the boundaries of the city to remove the black voters. The state legislature obliged and transformed the city’s border from a simple square to what the Supreme Court of the United States described in Gomillion v. Lightfoot (1960) as an “uncouth” twenty-three-sided figure. The Supreme Court declared that this transformation of Tuskegee amounted to a denial of the black residents’ right to vote.

In 1965 the U.S. Congress passed the Voting Rights Act. When it was amended in 1982, it was read by the Justice Department and the Supreme Court (in Thornburg v. Gingles, 1983) to require states to create legislative and congressional districts with voting majorities comprised of minority voters (“majority-minority districts”) wherever possible.

With this decision the Supreme Court essentially endorsed a congressional mandate to gerrymander legislative and congressional districts to help minority voters. While the Voting Rights Act was thus regarded as a benevolent attempt to rectify a heinous history of disenfranchisement of minority voters, it nonetheless endorsed a policy of officially mandated manipulation of the electoral system.

Beginning in 1993 with the decision in Shaw v. Reno, the Supreme Court retreated from its holding in Gingles. In so doing, it placed restrictions on the extent to which the federal government could require states to gerrymander districts on behalf of minority voters. While congressionally mandated gerrymandering was clearly benign in its intent, it was nonetheless a clear perversion of the electoral system.

Gerrymandering is unavoidable because it is impossible to draw electoral district lines or change electoral laws without having a clearly favorable or unfavorable impact on someone. Gerrymandering occurs throughout the world and in many different circumstances. Drawing on examples from the United Kingdom and Ireland, Richard Katz (1998) notes that in countries that use other electoral systems (such as proportional representation systems with multimember electoral districts), the size of districts can be manipulated so that particular parties end up wasting their votes and electing fewer candidates than they would in a district of a different size.

In addition, an electoral system can be gerrymandered by making it harder for minor political parties or independent candidates to challenge the established political powers. In Canada, for example, the Supreme Court has heard challenges to laws restricting the access of small political parties to government funds (Figueroa v. Canada, 2003), restricting campaign spending (Harper v. Canada, 2004), and allowing for great population discrepancies among voting districts (Reference re Provincial Electoral Boundaries [Sask.], 1991). The first two cases embodied claims that laws unfairly favored incumbent political parties by making it harder for minor political actors to garner enough influence to challenge the government. This not only discriminated against minor parties, it also rendered political competition less robust and the electoral system correspondingly unfair. In the Saskatchewan case, challengers claimed that population disparities among electoral districts unfairly favored rural interests at the expense of urban voters.

In conclusion, the term gerrymander has transformed since the mid-twentieth century from a reference to bizarrely shaped electoral districts to a broader term addressing myriad ways in which an electoral system can be rendered less competitive in hopes of achieving partisan gain. As a result, around the world, the trend is to place the authority to make changes to the electoral system in the hands of nonpartisan commissions or agencies.

Gestalt Psychology

Mark Rush

GESTALT PSYCHOLOGY

Gestalt theory, a major school of psychology during the first half of the twentieth century, was an influential counterpoint to the other mostly atomistic psychological systems of the time: structuralism, functionalism, and behaviorism. While its controversies with these other systems during the “age of schools” in psychology have receded into history, its major tenets once again became salient toward the end of the twentieth century in such fields as social psychology, cognition, personality psychology, and visual neuroscience.

Gestalt psychology proposed a radical revision of the atomistic view that had prevailed for centuries in Western science and social science. Natural wholes, according to the Gestalt view, are not simply the sum total of their constituent parts. Rather, characteristics of the whole determine the nature of its parts, prescribing the place, role, and function of each part in the unified whole. The Gestalt principle of Prägnanz, furthermore, asserts that the organization of any whole will be as “good” (i.e., balanced, simple, integrated) as the prevailing conditions allow. This insistence on holistic processes applies equally to all integrated wholes, from physical systems such as electrical fields, magnetic fields, and soap films to psychological systems such as cognitive processes, the organization of perception, personality, and social phenomena.

The Gestalt movement is generally viewed (Ash 1995; King and Wertheimer 2005) as having been launched by a series of experiments by Max Wertheimer (1880–1943) on apparent movement published in 1912, although clear indications of a Gestalt perspective were already evident in two earlier publications of Wertheimer on musical structures (1910) and on aboriginal thinking about numerical issues (1912). Two of Wertheimer’s colleagues who served as observers in these experiments, Wolfgang Köhler (1887–1967) and Kurt Koffka (1886–1941), became his collaborators during the next decades in promulgating the new Gestalt approach (Köhler 1929; Koffka 1935). A typical experiment in Wertheimer’s series involved, for example, exposure of a short vertical line in the visual field, followed after a brief interval by exposure of a second similar vertical line a short distance away from where the first one had been exposed. If the time and distance relations are appropriate, observers see a single line moving from one location to the other. The experience is indistinguishable from watching an actual short vertical line move from one location to the other; in both cases, the perception of motion is immediate and compelling. The prevailing alternate theoretical orientations, maintaining that percepts always correspond with their correlated physical stimuli, could not explain the perceived motion when the actual stimuli are two stationary lines successively exposed. The whole, the experience of motion as a Gestalt, cannot be derived from a combination of the “component sensations” of the two stationary stimuli.

The Gestalt school became prominent in European and American psychology. Its principles of perceptual organization have been summarized in almost every introductory psychology textbook; Wertheimer’s book Productive Thinking (1945) challenged the computer models of the late twentieth century to try to account for the ubiquitous cognitive processes of insight and understanding.

GESTALT THERAPY

Gestalt therapy is a therapeutic approach in psychology that helped foster the humanistic theories of the 1950s and 1960s and that was, in turn, influenced by them. In Gestalt philosophy, the patient is seen as having better insight into himself or herself than the therapist does. Thus, the therapist guides the person on a self-directed
path to awareness and refrains from interpreting the patient's behaviors. Awareness comprises recognition of one's responsibility for choices, self-knowledge, and ability to solve problems.

Its originators, Frederick S. (Fritz) Perls (1893–1970) and Laura Perls (born Lore Posner, 1905–1990), were born in Germany and studied psychology there. They fled Germany during the Nazi regime, moving to South Africa and then to New York City. They were both initially influenced by Sigmund Freud's psychoanalytic approaches and by Wilhelm Reich's Orgonomic psychotherapy. Their later ideas on Gestalt therapy broke with the psychoanalytic tradition, moving toward existentialism and, ultimately, humanism.

In New York City the Perls founded the Gestalt Therapy Institute in 1952. Their novel technique in therapy was to face the patient, in contrast to the typical Freudian technique of sitting behind a reclining person. The face-to-face positioning permitted the therapist to direct the patient's attention to movements, gestures, and postures so the patient could strive to gain a fuller awareness of his or her immediate behaviors and environment. Another well-known approach introduced in Gestalt therapy is the so-called “empty chair technique,” in which a person sits across from and talks to an empty chair, envisioning a significant person (or object) associated with psychological tensions.

By using these techniques, the Perls believed, the patient would be able to gain insight into how thoughts and behaviors are used to deflect attention from important psychological issues and would learn to recognize the presence of issues from the past that affect current behavior. The aim was for the patient to experience feelings, not to gain insight into the reasons for them, as psychoanalysts favored.

In the evolution of their therapy, Laura and Fritz Perls differed in some of their approaches. Laura emphasized more direct, physical contact and movement than Fritz did, and the contact favored by Fritz Perls was more symbolic than physical.

Gestalt therapy took its name from the school of academic psychology called Gestalt psychology. Perls asserted that Gestalt psychology had influenced the development of his ideas, but the Gestaltists claimed that there was no connection between the two. Later scholars suggested a common substrate linking the academic Gestalt psychology of Max Wertheimer (1880–1943), Wolfgang Köhler (1887–1967), and Kurt Koffka (1886–1941) and the Gestalt therapy of the Perls and their collaborators Ralph Hefferline (1910–1974) and Paul Goodman (1911–1972). This commonality involved appreciation of the whole rather than a reductionistic approach to understanding psychological phenomena and behavior.

Gestalt therapy took form in the 1950s and 1960s, when humanism first flourished. The optimistic theory promulgated by the Perls was quite compatible with the ideas of other humanistically oriented psychologists such as Carl Rogers (1902–1987). Its influence has waned since the 1980s, although current therapies have been influenced by the humanistic and optimistic outlook of the theory and by some of the interactive techniques developed by the Perls and their followers.

**GHETTO**

Social scientists have long studied the effects of economic, political, and social inequality on lives, attitudes, and behavior. Central issues in this research include how and why societies tend to treat certain groups negatively, how such groups respond to such conditions, and whether and how society should address the historic and contemporary social problems that result. The history of ghettos provides an exemplar of the effects and implications of differential treatment of minority groups in society.

The term *ghetto* has been historically used to describe legally sanctioned segregated areas occupied by ethnic minorities. Although some writers contend that the first ghettos were created to segregate Jews during the Roman Empire between the first and fourth century CE, the term is most commonly used to describe segregated Jewish sections in Italy, Germany, and Portugal in the 1200s. The translation of the term *ghetto* originally referred to the Venice Ghetto in the 1300s and areas of town that were originally iron foundries or *gettos* before being converted to secluded Jewish sections. The term is also translated “gated” to characterize residentially isolated neighborhoods that existed in Venice and parts of northern Italy until as late as the 1600s. Other derivatives of the term refer to a small neighborhood (Italian, *borghetto*) or a “bill of divorce” (Hebrew, *get*). As suggested by these translations, it was illegal for non-Jews to live in ghettos and Jews...
Ghetto

were prohibited from leaving. To impose these sanctions, the gates of this section of the town were locked at night.

Roman ghettos were created in the mid-1500s via a decree by Pope Paul IV (1476–1559) and lasted until the Papal States were overthrown by Italy in 1870. Roman ghettos were used to separate Jews from Christians, but also enabled the Jewish community to maintain its religious and cultural practices and avoid assimilation. Other Jewish ghettos were located in Prague, Frankfurt, and Mainz. Although legal restrictions were no longer imposed in Europe during the 1800s, many ghettos continued to exist based on cultural or religious dictates. Most European ghettos were destroyed in the nineteenth century following the French Revolution. However, the rise of Adolf Hitler (1889–1945) in Nazi Germany in the twentieth century saw the return of Jewish ghettos in eastern European cities. Other international ghettos include the predominately black area of Soweto in Johannesburg, South Africa; KwaMashu in Durban, South Africa; and ghettos in the United States in South Central Los Angeles, sections of Chicago, and rust-belt cities such as Flint, Michigan.

GHETTOS IN THE UNITED STATES

Ghettos in the United States are generally defined as poor inner-city areas where a disproportionate percentage of ethnic minorities reside. Although African Americans are generally associated with ghettos, Hispanics and whites also live in them. Ghetto neighborhoods are also defined as census tracts where 40 percent or more of residents, regardless of their race or ethnicity, are poor. The latter definition is widely used for comparative purposes in quantitative urban sociological research. Although ghetto residents tend to be ethnic minorities, it is important to note that neighborhoods where a large number of ethnic minorities reside are not necessarily ghettos. For example, prior to deindustrialization, many African Americans were segregated in northern communities such as Chicago’s Bronzeville. Although the area was predominately African American, it was also the place of residence for relatively affluent African American families and businesses. Furthermore, economically stable ethnic enclaves such as Chinatowns and Germantowns exist in many cities across the United States.

The distinguishing factor that generally constitutes a ghetto is the prevalence of poverty. Ghettos are also often distinguished from other racially or ethnically homogeneous communities (for example, a predominately white or black suburban area) because of the inability of many residents to relocate from ghettos—even if they desire to do so. Poverty among many U.S. ghetto residents makes it difficult to out-migrate. The involuntary nature of ghetto areas often reflects constrained residential choices less evident in non-ghetto locales. Thus, as compared to historic ghettos that were formed due to direct or indirect racial or ethnic coercion and isolation, contemporary U.S. ghettos generally reflect class-based formation and the resulting isolation.

U.S. ghettos developed as a result of dramatic postindustrial economic, political, and social changes. Several urban migrations during the early and mid-twentieth century resulted in the exodus of many African Americans to such northern states as Illinois, New York, Michigan, and Pennsylvania in search of employment and to escape segregation and discrimination in the rural South. During the same period, persons of Hispanic descent migrated from Puerto Rico, Mexico, and Central and South America to New York, Miami, and Chicago for similar reasons. Cities provided industrious, less-educated persons with manufacturing jobs to earn a family wage.

After World War II (1939–1945), globalization and deindustrialization resulted in significant international and national economic restructuring. The United States responded to increased international economic competition by spurring technological advances and relocating industrial enterprises abroad and to the suburbs to increase profits. Increased efficiency and fewer manufacturing positions unduly affected residents in northern cities—especially ethnic minorities. From about 1967 to 1987, cities such as New York, Chicago, and Detroit lost more than 50 percent of their manufacturing jobs. By the late 1900s, many persons who had been gainfully employed in northern industrial cities became unemployed or underemployed or were forced to work in service occupations for substantially lower wages and reduced benefits.

The dramatic decline in manufacturing jobs affected a disproportionate percentage of African Americans and Hispanics. The out-migration of manufacturing firms coupled with an exodus of middle-class families and other businesses from cities to suburbs and abroad left many inner cities economically devastated. Economic restructuring coupled with the effects of poorly underserviced infrastructures, inadequate housing to accommodate a growing urban populace, group conflict and competition over limited jobs and space, the inability for many residents to compete for new technology-based jobs, and tensions between the public and private sectors led to the formation and growth of U.S. ghettos. Furthermore, housing discrimination in the form of redlining by lending institutions, discriminatory practices by realtors, and the development of large housing projects resulted in densely populated urban locales of primarily poor ethnic minorities. Economic challenges were exacerbated by the effects of historic and contemporary classism, segregation, and racism. The cumulative effects of these systemic forces
contributed to the existence and prevalence of concentrated urban poverty in many U.S. ghettos.

**CONDITIONS IN GHETTOS**

Ghettos were historically developed to physically isolate a group with clearly identifiable physical features and cultural markers. Contemporary U.S. ghettos have had similar effects on many African American and Hispanic residents. Whether the result of legal sanctions or due to societal norms and values, physical isolation in ghettos usually results in social, political, and economic isolation. Such separation also directly or indirectly conveys superior status and privilege on majority group members and, by default, inferior status and privilege on the segregated group.

Although the Venice Ghetto was actually a relatively wealthy section of town where moneylenders and merchants resided, overall, conditions in ghettos were and continue to be negative. Jews could maintain their cultural and religious practices, but a segregated existence meant political and social isolation from the larger society. Because Jews could not purchase land outside the ghetto, population increases resulted in overcrowded conditions and infrastructure problems characterized by narrow streets and tall houses. Jews were allowed to organize and maintain their own political system within the ghetto. However, they often needed official passes to travel outside the ghetto walls.

The Warsaw Ghetto of Nazi Germany housed almost 400,000 Jews and was the largest and possibly most notorious ghetto. These ghettos were walled off, and Jews were shot if they attempted to escape. Other horrific conditions included extreme overcrowding, limited food supplies rationed by the Nazis, poor sanitation, starvation, and disease. Jews who survived these circumstances were forced to contend with the ever-present threat of death or deportation to concentration camps. In 1942 systematic efforts were implemented to deport Jews from ghettos around Europe to eastern ghettos or to concentration camps such as Treblinka in Poland. Historians suggest that various direct and indirect ghetto uprisings broke out, but the majority of residents in the ghettos of Nazi Germany were killed.

Contemporary ghettos are generally characterized by neighborhood and household poverty, social isolation, segregation, discrimination, overcrowding, increased crime, neighborhood disinvestment, and political disempowerment. Ghetto residents are more likely to live in substandard housing, frequent understaffed hospitals and healthcare providers, and have limited access to gainful employment. Businesses such as grocery stores, banks, retailers, and other institutions needed to complete the daily round are also limited and often overpriced or underserviced as compared to their suburban counterparts. Children who reside in ghetto areas tend to attend ill-equipped schools and must often learn at an early age to negotiate potentially crime-ridden neighborhoods. Research also suggests that the life chances of many ghetto residents are constrained largely because their place of residence isolates them from important resources needed to locate gainful employment, establish informational networks, and interact consistently in the larger society. Political disenfranchisement in ghettos is usually a result of isolation by predominately white state-run governments from predominately ethnic minority residents in ghetto spaces. Although studies show that most ghetto residents subscribe to mainstream values and goals, limited opportunities and resources often constrain their chances to realize them.

Urban renewal efforts are underway in many inner-city ghettos—with varied results. In some instances, renewal has resulted in refurbished neighborhoods, increased tax bases, and strengthened infrastructures. Supporters of urban renewal efforts point to the in-migration of young professionals as an important factor in revitalizing ghettos. However, detractors suggest that gentrification benefits persons who in-migrate and are able to use their greater discretionary income to take advantage of depressed housing markets at the expense of existing, poor ethnic minorities who are often forced out of their homes because they cannot afford to live in the newly renovated, higher-taxed neighborhoods.

Research is inconclusive regarding exactly how to characterize experiences in contemporary ghettos. The prevailing economic, political, and social disenfranchisement does not suggest a positive portrait of life. However, studies attest to the adaptive, resilient nature of many residents that belie the harsh reality of their experiences. A comprehensive discourse on the effects and implications of ghetto life and needed interventions should consider the challenges associated with ghetto living, the strengths of persons who live in ghettos, and the role the larger society should play to improve ghetto conditions.

**GIDDENS, ANTHONY**

**1938–**

Anthony Giddens was educated as a sociologist at Hull University and the London School of Economics (LSE). He held a lectureship at Leicester University before being appointed lecturer and subsequently professor of sociology in the University of Cambridge. In 1996 he left Cambridge to become director of the LSE.

Giddens was certain at the end of the 1970s that nineteenth-century thought, on certain themes of which sociology had tended to remain focused, was an inadequate basis on which to proceed. In particular, Talcott Parsons's (1902–1979) theory of the mid-twentieth century, supposedly resolving the main questions associated with these themes, had degenerated into an objectivistic, teleological framework in which the original “action” element had been lost, whilst his “interpretivist” opponents, while dealing with action and interaction, were unable to conceptualize “structure” in a satisfactory way. For Giddens, redressing these issues in *The Constitution of Society* (1984), agency and structure are not merely mutually implicated in the sense that “structure” involves agents acting and acting is inconceivable apart from “conditions” and unintended consequences, they are the same. They merge in “practice.” Structure is virtual. It exists only in doing, moment by moment. This virtual “rules and resources” is “instantiated” and simultaneously reproduced in the action it “recursively” permits, as actors draw upon it to act, their concrete actions making up “social systems.” For critics of this, such as Margaret Archer (1990) and Nicos Mouzelis, there are certain important advantages to be gained from retaining the dualism of structure and agency, and not conflating them, and this need not mean returning to a sterile opposition between objectivism on the one hand and subjectivism on the other: Agency and structure should be seen as interrelated, but also as different kinds of things. This is only the most fundamental of the arguments critical of Giddens’s work in all its aspects.

“Reflexivity” is at the core of Giddens’s structuration theory, appearing in the shape of the self-monitoring actor, taken over and adapted from radical subjectivism. Agents’ knowledge of the mechanism of system reproduction, used by them to control this reproduction, influences substantially the causal feedback loops effecting system reproduction. In *The Consequences of Modernity* (1990) this reflexivity moves into a more prominent position in Giddens’s thinking than it had previously held; he sees it as being at the heart of what he began to call “late” or “radicalized” modernity. For it was reflexivity, both of the actor and of the social institution, that was becoming stepped up as tradition retreated more than in the “modern” past in the face of social relations that were increasingly “stretched” globally and lifted out of communal and face-to-face settings. (“Distanciation” or “stretching” of social relations in both time and space to form ever more extensive social systems was central to structuration theory.) In this phase of his development Giddens returned to the sociological analysis of modernity, the point from which he professed to have started out, resuming the interpretation of modern society that had been begun with the critique of historical materialism in *A Contemporary Critique of Historical Materialism,* vol. 1 (1981), and continued with his analysis of the nation-state in *The Nation-State and Violence* (1985). The latest phase has seen Giddens turning to politics.

Giddens became convinced in the 1990s that the ideological positions of the “first” modernity had become frozen and increasingly out of touch with the current dethraditionalized, increasingly globalized social reality of the emerging “late” or “reflexive” modernity. The Left had become conservative in their clinging to the welfare state (the product of a now passed, post-war class compromise or social settlement) whereas neoliberal celebrants of the market were caught in the growing contradiction of advocating the advance of forces that undermined moral coherence, which they as conservatives also espoused. Giddens urged in *Beyond Left and Right* (1994) a “Third Way” between Left and Right. This was, for some, an imprecise set of recommendations attached to a vague idea. But Giddens did specify the need for negotiation in personal life and for a politics outside of the old structures: a “life politics” and a “generative politics,” as he called them, by means of which people could seize hold of their own lives, taking advantage of the opportunities created by globalization and the retreat of the nation-state, recasting them themselves in a social environment located always at some point between “trust” (security) and “risk” (perceived danger). Basic trust is for Giddens an essential part of personality development, but now more than ever it must be “worked for” in intimate relationships; it can no longer be as taken for granted as it once was, and, moreover, exten-
sive locality-transcending social relations simultaneously require and place in jeopardy, through its very integralness, trust—the opposite of which is risk. Giddens’s analysis of reflexive modernization was the key to the Third Way in ways spelled out in detail in *The Third Way* (1998)—for example, reflexivity in personal relations could form the basis for democratic renewal from the grassroots “upwards,” and reaching beyond the nation-state, and was central to the “life politics” that Giddens saw taking shape around him in a radicalized modernity, where the global and the local interpenetrate, and with new social movements displacing the old institutionalized parties and historic ideologies of an earlier industrial period.

Giddens’s action recommendations are locatable in his four institutional orders of modernity (industrialism, capitalism, administration-surveillance, and the military), but their principles could also be related, at least schematically, to the “rules” (signification and legitimation) and allocative and authoritative “resources” (domination) of his 1984 structuration schema. His influence on sociologists worldwide has been enormous, as is attested by the number of citations of his numerous works both scholarly and popular, the latter affecting parties and governments of a Third Way complexion. It is a measure of their author’s distinction that the issues they raise continue to be debated around the world.

**GIFTED AND TALENTED**

The history of gifted education is filled with controversy and concerns regarding how best to define and assess giftedness, and also how best to serve those who are deemed to be in need of gifted education programs and services. Gifted education programs in public schools have also received national attention as a result of the low percentage of culturally and linguistically diverse students identified as gifted and served in these programs.

**IDENTIFYING GIFTED STUDENTS**

Federal-level initiatives provide guidance for local and state gifted program policies and practice. The 1993 National Excellence Report provided a foundation upon which advocates of gifted education can be proactive in defining giftedness and identifying and serving gifted students. According to the report:

Children and youth with outstanding talent perform or show the potential for performing at remarkably high levels of accomplishment when compared with others of their age, experience, or environment. These children and youth exhibit high performance capability in intellectual, creative, and/or artistic areas, possess an unusual leadership capacity, or excel in specific academic fields. They require services or activities not ordinarily provided by the schools. Outstanding talents are present in children and youth from all cultural groups, across all economic strata, and in all areas of human endeavor. (USDE 1993, p. 27)

This definition may be the most culturally sensitive federal definition to date, with its focus on talent, potential, and comparisons of students of the same age who come from similar backgrounds and experiences. It also boldly states that giftedness exists in all groups, and that no group should have a monopoly on being identified and served.

In addition to developing this new definition of *gifted*, the Jacob K. Javits Gifted and Talented Students Education Program, enacted in 1988, supports demonstration grants, a national research center, and national leadership activities designed to focus attention on the needs of students with demonstrated or potential talent. It is now clear that conventional views of giftedness and traditional ways of identifying giftedness (e.g., using single IQ scores or standardized achievement tests) often create barriers for culturally and linguistically diverse and low-income students to gain access to gifted programs. Thus, the Javits Program is also important because priority funding is given to efforts to serve gifted and talented students who are economically disadvantaged, speak limited English, or have disabilities.

**GIFTED PROGRAMS AND RACISM**

Gifted education has encountered much criticism due to a legacy of racial inequality in the United States that has
often been tantamount to de facto segregation. Throughout its history, gifted education has not been truly desegregated. Rather, Hispanic American, American Indian, and African American students remain underrepresented by large percentages (see Table 1).

This historical problem is rooted in the deficit views of culturally diverse groups, as well as in the overreliance on intelligence tests as the single or primary means of selection. For example, in the early 1900s, many researchers who examined intelligence among students held the belief that culturally diverse children, particularly African American children, were innately inferior to white children (see Figure 1). In addition, many scholars maintained that poor children, regardless of race, were also intellectually inferior to white students from middle- and upper-income families. While scholars vehemently refuted the biased views that resulted from the use (or abuse) of intelligence tests, intelligence quotient (IQ) scores on standardized tests were used to reinforce and distort beliefs about the intellectual capacity of white children, and to perpetuate their superiority and worth within society.

The emergence of gifted education coincided with the end of the “separate but equal” doctrine, which was validated by the U.S. Supreme Court in *Plessy v. Ferguson* in 1896. This decision made it legal for white and black children to be educated in separate schools. As a result, white children generally went to schools of higher quality than black and other culturally diverse children. White children were believed to be innately higher in their capacity for academic achievement and educational attainment. They were also perceived to be smarter, more motivated, and more creative, and therefore more deserving of instructional services and facilities than black children, who, “by nature,” required less access to or need for quality educational opportunity or instruction. Genes were considered to be the main determinant of destiny, while the environment—including education—was deemed to be of little significance for blacks (see Herrnstein and Murray 1994).

Today, some scholars continue to criticize gifted education because it is viewed as serving a racist or elitist
agenda seeped in educational politics (see Sapon-Shevin 1993; Wells and Serna 1996). More than any other educational program in public schools, gifted education faces the ongoing struggle to desegregate its programs. As of 2002, for example, black students were underrepresented by 60 percent in gifted programs nationally. Essentially, segregation, as it existed almost two centuries ago, seems to still be evident in gifted education.

Essentially, while the Brown v. Board of Education court decision in 1954 ended legalized segregation in public schools, the politics of education made way for a new form of segregation through gifted education. Cloaked behind the guise of valiant goals—such as meeting the needs of talented youth and preparing the next generation to be competitive in global markets—gifted education programs have primarily provided services to white students from middle- and upper-income families. Indeed, the concept of the “gifted child” remains synonymous with white middle-class children in the minds of too many public school educators and parents. In many ways, the advent of gifted education pleased white parents who were angry at the social and political changes occurring in the educational landscape that mandated schools to integrate, and not only were white parents infuriated by their children being forced to learn with “inferior” and “disadvantaged” black children, they also opposed white children being educated by black teachers.

Gifted education is based on the general premise that students with a high level of intellectual ability, or who excel in specific academic areas, need special instructional services to achieve their full potential. In essence, special instructional services (e.g., accelerated classes, enrichment programs, advanced academic experiences) for students with outstanding talent are essential to meet the gifted student’s needs, just as special education services (e.g., remedial reading or tutoring) are essential for meeting the needs of students with learning disabilities. However, because of the historical racial inequity in programs for gifted students, gifted education still lacks essential support because it is seen as a modern form of promoting separate and unequal education. For example, the field of gifted education is plagued by the reality that standardized IQ testing, which was the primary tool that researchers used to perpetuate the inferiority of blacks and the superiority of whites, is still the primary method by which black and other diverse students are kept out of gifted programs.

Why do some want to keep gifted education segregated? Gifted students often receive the best instructional resources, the most effective or qualified teachers, and the lowest student-teacher ratios, all of which are critical to a quality education. Therefore, some parents may not want their children to remain in general education; they may aggressively push to have their children in gifted programs, even if they do not meet criteria. Further, some administrators may resist admitting more diverse students into gifted education classes if parents and community members are resistant to diversifying gifted (and advanced placement) classes, as has been found in several court cases investigated by the Office for Civil Rights.

To address the historical inequality in the representation of ethnic minorities in gifted education, the National Association for Gifted Children (NAGC) is being proactive by building upon the legacy of Dr. Mary M. Frasier, an early pioneer for underrepresented groups in gifted education. The primary purpose of NAGC’s Mary Frasier Teacher Scholarship Fund for Diverse Talent Development is to increase culturally and linguistically diverse students’ access to talent development opportunities through teacher training and support related to equity and excellence in gifted education. In addition, several scholars continue their efforts to eliminate identification criteria that adversely affect the representation of diverse students in gifted education.

GILDED AGE

Mark Twain and Charles Dudley Warner’s The Gilded Age (1873), a satire of Americans’ rush for material gain and political corruption in the years immediately following the Civil War, provided succeeding generations with a ready frame of reference for this period. Many historians’ examinations of this era emphasized the political parties’ keen competition and how the ruthless, if innovative, industrialists that Matthew Josephson dubbed “the robber barons” used a compliant federal government to build vast fortunes from the United States’s abundant natural resources. For several generations the Gilded Age (1866–1900) received far less attention from students of history than other eras in American history. But in recent years historians have argued that, together with the decades known as the Progressive Era (roughly 1900–1919), it represents a central chapter in the history of the United States. Examining aspects of American life beyond the robber barons and party politics, these accounts have shown how in these years Americans built a modern nation and grappled with its consequences.

The Gilded Age marked a major watershed in the history of American race relations. Historians have shown how in the period between the Civil War and the turn of the twentieth century white Americans decisively rejected the Civil War and Reconstruction’s seeming promise of racial equality, and subjected African Americans, Chinese Americans, and other racial minorities to new systems of segregation, discrimination, and domination, as well as elaborate cultural rationales for their development.

In an industrial economy marked by severe depressions, a growing number of wage laborers found themselves seemingly consigned to lives of bitter toil with little hope for advancement. Many responded by struggling to build trade unions to represent their interests in dealings with employers, but faced judges and other public officials eager to promote business interests as representing the common good. In this context, employers and workers engaged in a series of violent clashes. These episodes led many intellectuals and members of the well-to-do and middle classes to perceive a fundamental crisis in American public life, a sentiment that informed both government officials’ vigorous repression of strike activities and the rise of movements seeking reform through legislation and voluntary action.

An urban-industrial society characterized by increased wage labor and salaried professional work also manifested major changes in gender relations. Earlier in the nineteenth century many women had identified themselves as occupants of a “separate sphere” quite removed from public life and characterized by child-rearing and moral insight. But in the Gilded Age, growing numbers of women used their imputed status as moral arbiters to assert themselves in public life, even if they could not vote. While some continued to seek the ballot, others constructed reform organizations such as the Women’s Christian Temperance Union to influence individual behavior and public policy through persuasion.

A new synthesis of scholarship on the Gilded Age has identified this period’s nation-building dynamic as a multifaceted process of “incorporation.” In addition to establishing effective control over many of their wage workers, managers of many large corporations also used their size and scope to establish significant advantages over their suppliers and customers in the marketplace. Government officials systematically removed Native Americans from the American West’s more attractive locales to a set of reservations in this period. American officials extended this geographic dynamic of incorporation by making the Hawaiian Islands a territory and assuming Spanish colonial possessions, most notably the Philippines, after a one-sided conflict in 1898. In one sense these activities represented a nation-state exerting control over captured territories. But while Americans’ development of elaborate theories for the subjugation of members of other races also represented a cultural process of incorporation. Many historians have concluded that these activities represented a desperate attempt to lend some semblance of hierarchy to a modernizing, democratic society increasingly breaking down more familiar sources of order, ranging from
simple geographic isolation to differences in education and literacy to slavery itself. Where many earlier scholars of the period described political corruption largely redeemed by the Progressive Era’s reforms, the emerging synthesis has elaborated an alternative view of American national development, highlighting pervasive patterns of exclusion and injustice only partly mitigated by federal regulations and the mass social movements of the mid- to late twentieth century. A significant number of scholars continue to examine the dynamics of political corruption and reform, as well as other aspects of political, economic, and intellectual history. But in the early years of the twenty-first century this new synthesis has placed the Gilded Age firmly at the center of American historical discourse.

GILLIGAN, CAROL

1936–

Carol Friedman Gilligan was born November 28, 1936, in New York City. Her book *In a Different Voice* ushered in an era of research and theory about gender differences that valued the voices of girls and women.

Gilligan grew up in New York City. She went on to do her undergraduate work at Swarthmore College, where she majored in English and history, graduating summa cum laude in 1958. She earned a master’s degree in clinical psychology from Radcliffe College in 1960 and a PhD in social psychology from Harvard in 1964. She began teaching at Harvard with the psychologist Erik Erikson in 1967 and continued teaching at Harvard’s School of Education, receiving tenure as a full professor in 1986. During her early years at the School of Education she co-taught a course with Lawrence Kohlberg, whom she considered a friend (although many biographies wrongly describe her as his student). As a teacher in the 1980s at the School of Education, she taught courses on the psychology of moral development and adolescence and was known for lectures integrating literature, mythology, biography, and history. In 1997 Gilligan was appointed to a newly endowed professorship at the Harvard Graduate School of Education, the Patricia Alsbjerg Graham Chair in Gender Studies, Harvard University’s first position in gender studies. In 2002, shortly after the announcement of a 12.5 million dollar grant to the School of Education from Jane Fonda, who stated she was inspired by Carol Gilligan’s work, Gilligan joined the faculty of New York University as a full-time professor in the schools of education and law.

In *In a Different Voice: Psychological Theory and Women’s Development* (1982), Gilligan identified a kind of moral reasoning that was based on an ethic of care rather than an ethic of justice. Although the ethic of care has been identified as women’s moral voice, the “different voice” Gilligan describes is “characterized not by gender but theme. Its association with women is an empirical observation, and it is primarily through women’s voice that I trace its development” (p. 2). The voices of women and girls, she claimed, had been neglected by those who studied morality, such as Piaget and Freud. She pointed out first that these men and others based their theories of human development on a male model of separation and individuation, often studying, observing, or speaking only to boys and men and later describing as an afterthought how girls and women did not fit the norm. In this groundbreaking book, Gilligan criticized the work of Lawrence Kohlberg (whose theory was based on a study that included only adolescent boys), because women, in his six stages of moral development, seemed unable to advance beyond Stage 3, also known as the “good boy/nice girl stage.” Kohlberg’s research showed more men than women advancing to stages in which they preferred to use a morality that was based on contracts, individual rights, justice, and even what he called a universal morality; females were more likely to remain in adulthood in the so-called “conventional” morality stages. Through several studies that included interviews discussing Kohlberg’s moral dilemmas as well as what Gilligan called “real-life” dilemmas, she showed girls and women to be responding not only to issues of justice, but issues of care. Although the point was not elaborated in *In a Different Voice*, she later argued that women’s association with stage 3 was not structural, but a function of patriarchy. She then further developed the cultural/social side of her argument and the element of resistance so key to her work with girls. Over time Gilligan’s work has been inaccurately described as suggesting that women are more caring than men. Rather, she argues that women are more likely to make moral decisions based on issues of care, inclusion, and personal connection, rather than on a more abstract and distant notion of justice.

The methodological shortcomings in others’ works that Gilligan critiqued in *In a Different Voice* were the
impetus for new research methods used and developed in Gilligan’s later work and in the work of her students. In this work she and those influenced by her continued to fault researchers for using a male perspective as a starting point. She also encouraged the increasing use of open-ended interviews focused on self in relation to a range of issues, an approach that had largely been dismissed as producing suspect “self-report” data. In addition, her work valued qualitative, thematic analysis. The “Listener’s Guide,” written with Lyn Mikel Brown, describes a voice-sensitive method attuned to a psyche in active dialogue with the sociopolitical realities of everyday life.

Following her publication of In a Different Voice, Gilligan herself continued to pursue qualitative research exploring the relational world of girls, resulting in Meeting at the Crossroads (1992), coauthored with Brown, and Between Voice and Silence: Women and Girls, Race and Relationship (1996), coauthored with students Jill McLean Taylor and Amy M. Sullivan. She has helped guide the work of former students, such as Janie Victoria Ward (The Skin We’re In, 2000), Dana Jack (Silencing the Self, 1991, and Behind the Mask, 1999), Deborah Tolman (Dilemmas of Desire, 2003), Niobe Way (Everyday Courage, 1998), and Lyn Mikel Brown (Raising Their Voices, 1998, and Girlfighting, 2005). Her work has also been influential in feminist discourse theory, law, medicine, and philosophy. Gilligan was a founder of the Harvard Project on Women’s Psychology and Girls’ Development, and of Strengthening Healthy Resistance and Courage in Girls, a prevention project that also was expanded to include boys and men as her interests shifted to examine the plight of boys in Western society.

Gilligan’s 2002 book The Birth of Pleasure summarizes themes of love and caring that were suggested in earlier work. Using the Cupid and Psyche myth as the quintessential Western love story, she discusses familiar themes of the objectification of women, the pitting of woman against woman in patriarchy, men's fear of the intimacy they long for, and “dissociation”—or the process by which women learn to forget or cover over what they know to be true and by which men learn to replace feelings of vulnerability and tenderness with masks of masculinity.

In 1992 Gilligan, the recipient of numerous awards, was given the prestigious Grawemeyer Award in Education. This is given to honor achievements in areas not recognized by the Nobel prizes. She was also named one of Time Magazine’s twenty-five most influential people in 1996. In 1997 she received the Heinz Award for knowledge of the human condition and for her challenges to previously held assumptions in the field of human development.

GINI COEFFICIENT

The Gini coefficient is the most popular measure of inequality in use today. The measurement is named for its developer, Corrado Gini (1884–1965), and is based on the Lorenz curve (Sen 1997; Xu 2004). Although the Gini was traditionally used to measure income as a measure of welfare, it is now often used to measure other variables such as expenditures, wealth, and even health.

The clearest way to portray the Gini coefficient is diagrammatically. Take a population of ten individuals, as shown in Table 1. If you sort the population from poorest to richest and graph the cumulative share of income against population, what you get is a Lorenz curve, as depicted by the curve in Figure 1. If every individual in the society had equal income, the graph would be the diagonal. But in any society, the poorest will have a share less than their proportion in the population, so the Lorenz curve will always be below the diagonal. The Gini coefficient is measured as the ratio of the area between the diagonal and the Lorenz curve (X) and the area under the Gini Coefficient

Table 1
diagonal \((X + Y)\). The formula for the coefficient can be stated as

\[
G = \frac{1}{2n^2\mu} \sum_{i=1}^{n} \sum_{j=1}^{n} |y_i - y_j|
\]

where \(n\) is the population, \(\mu\) is the mean of incomes, \(y\) is income, and \(i\) and \(j\) are individuals in the population. This is effectively a sum of all pair-wise income inequalities in the population. The Gini coefficient is, thus, a measure of the overall inequality in the population (Sen 1997).

In Table 2 and Figure 2, in addition to the original distribution used above (labeled as \(B\)), we add two other distributions (\(A\) and \(C\)). As income inequality increases, the Lorenz curve moves farther away from the diagonal (see distribution \(C\)), and the opposite occurs as inequality decreases (see distribution \(A\)). In a society where income is equally shared, the area \(X = 0\) because the Lorenz curve would coincide with the diagonal and the Gini coefficient would equal 0. In contrast, if all income is held by the richest individual in society, then \(Y = 0\) and the ratio would equal 1. The Gini coefficient thus always lies between 0 and 1. The most common convention nowadays is to multiply the ratio by 100 and then report the Gini coefficient as a number between 0 and 100. One of the great strengths of the Gini is that any redistribution of income from a poorer person to a richer person results in an increase of the coefficient, and thus it captures distribution across the entire population rather than just at the mean.

Despite its popularity, the Gini suffers from the fact that there is no intuitive meaning to any particular magnitude of the coefficient. Nor does any specific magnitude represent a unique distribution. A Gini of 30, for example, can represent two different distributions, and there is no objective way to differentiate the distributions. This occurs because Lorenz curves may cross. It follows from this that determining distributions that are highly unequal versus those that are not is more an empirical question.

Table 2
In order to give the reader some sense of what levels of inequality different sizes of Gini represent, Table 3 illustrates the average Gini coefficients and the average level of income accruing to each quintile of the population for thirty-eight countries, from a dataset compiled by Klaus Deininger and Lyn Squire (1996). The thirty-eight countries were picked because they had a measurement of Gini that Deininger and Squire considered reliable and comparable across countries between 1990 and 1995, as well as information on the quintile distributions of income, which gives us more information on the underlying distribution. If we divide the countries evenly into three groups we find that the group with lowest inequality has Ginis that range from 22 to 30, the middle group from 31 to 34, and the most unequal group from 35 to 62. Because this last group has such high variation we divide the group into two at 45.

Although these observations do not encompass the whole range of measured distributions, they do provide us with some more information. On average, developing countries, particularly in Africa and Latin America, dominate the group of highly unequal countries, whereas the group of low inequality is dominated by European countries, particularly those that formerly belonged to the socialist bloc. For countries with low inequality, the richest 20 percent of the population earned less than 40 percent of national income, whereas for those with high inequality the richest earned over 47 percent, averaging close to 60 percent. In contrast, for the poorest 20 percent in the low-inequality countries earned between 7 and 11 percent of national income, whereas in the highly unequal countries they only earned between 2 and 4 percent of national income.

Since the late 1980s a number of strides have been made in estimating the Gini from functional forms including the diagrammatic methods discussed above, as well as in decomposing it so that one can estimate the impact of different components of income on inequality. For a good summary of this literature, see Xu (2004).

</table>
GINZBERG, ELI  
1911–2002

Eli Ginzberg was born in New York City, the son of prominent rabbi Louis Ginzberg and the former Adele Katzenstein. He was the great-great-grandnephew on his father’s side of the “Vilna Gaon,” an eighteenth-century rabbi, Talmud scholar, kabbalist, and mathematician. The Vilna Gaon had studied Euclid, caused one of his students to translate Euclid into Hebrew, and was the author of “A Ram in Three Parts,” a mathematical analysis of Genesis 15:9. His followers initiated the modern Zionist movement. The family thus belonged to the intellectual, political, and financial elite of the Jewish community.

Ginzberg earned the AB, AM, and PhD from Columbia University in 1931, 1932, and 1935, respectively. Wesley Clair Mitchell and E. R. A. Seligman were his principal mentors, and his graduate schoolmates included Abram L. Harris Jr., Joseph Dorfman, and Robert Dorfman.

Ginzberg’s career may perhaps be best categorized as that of an entrepreneurial statesman of economic ideas in academia and government. Upon receiving the doctorate, he joined the economics faculty of Columbia Graduate Business School, remaining until his 1979 retirement. There, Ginzberg uniquely focused his research and teaching on labor, health, and race policy issues in economics. He taught three courses or seminars per semester for more than thirty-three years. He also was given occasional responsibilities in the Graduate Department of Economics, College of General Studies, Barnard College, College of Physicians and Surgeons, and the School of Public Health. In 1938, he and Mitchell offered a seminar titled Economic Change and Economic Theory in the economics department. In the School of Public Health he taught Political Economy of Health Care.

During World War II, Ginzberg served the United Jewish Appeal and many agencies in the federal government, including the White House and the surgeon-general’s office. At the Five-Power Conference on Reparations for Non-Repatriable Victims of Germany in June 1946, he served as a U.S. delegate. He was awarded the medal for Exceptional Civilian Service from the War Department in 1946. As a consultant to the U.S. Army from 1946 to 1955, he played a role in the army’s desegregation.

Back at Columbia Business School in 1950, Ginzberg was appointed director of the Eisenhower Center for the Conservation of Human Resources, a position he held until 1979. He was promoted to full professor in 1952.

He was involved with the establishment of the National Institutes of Mental Health (NIMH), being appointed a member of the National Mental Health Advisory Board in 1959. NIMH funded the nation’s first community-based advocacy planning institute in Brooklyn in 1968, a project that employed black Columbia and Yale graduate students in economics and a White House Fellow. He was involved with the establishment of Medicare and Medicaid in 1965.

Ginzberg published at least 179 books and hundreds of articles, which may be categorized into six major themes: (1) history of economic thought, 2) labor economics, (3) industrial organization, (4) race and economics, (5) autobiography and biography, and (6) health economics.

His writings in the history of economic thought included “Studies in the Economics of the Bible” in the Jewish Quarterly Review (1932), the first systematic treatment of biblical economics since Adam Smith; his dissertation, “Adam Smith and the Founding of Market Economics” (1934); The House of Adam Smith (1964); The House of Adam Smith Revisited (1977); “Economics at Columbia: Recollections of the Early 1930s” (1990); and “Wesley Clair Mitchell” (1997).

In labor economics, Ginzberg’s most important contributions were a theory of occupational choice and a general theory of the development and use of human resources. Most of his publications in this area addressed federal labor policy issues. He also served on the National Advisory Committee on Manpower Development and Training from 1962 to 1982.
Ginzberg's works in industrial organization contain his most important theoretical contributions. He developed the concept of a pluralistic economy including private, public, and nonprofit sectors, thus adding an explicit third sector to the private and public sectors of the mixed capitalist-socialist economy. The concept of the coequal third sector was the most striking view of the structure of a modern economy since Marx. It spawned a still growing international literature on the economics of nonprofit organizations (including most notably hospitals and universities) as a macrosector. Many interesting implications for welfare economics flooded the literature, led by Burton A. Weisbrod of the University of Wisconsin. Weisbrod argued that these organizations were substitutes for markets that had “failed,” so they assumed the functions of the market. Others argued that participants in such organizations did not seek to optimize objective functions but only “satisficed.” Despite the empirical reality and growing significance of this sector, however, and the novelty of explanations for its existence, this literature may nevertheless be considered simply a more highly theoretical form of the utopian socialist literature of the early nineteenth century. In 1985 appeared the most interesting of all Ginzberg’s works, Beyond Human Scale: The Large Corporation at Risk, with George Vojta. It showed the similarity of economic relations among micro-units of a macro-unit among such large-scale, complex organizations as corporations, the military, the Catholic Church, universities, and hospitals. The authors uniquely use the example of not-for-profit institutions whose pricing structures are “hidden,” that is, utilize “transfer prices.” Although explicit recognition of such prices dated to the 1890s and their naming to the 1950s, this was the first analysis of their implication for nongovernmental non-profit organizations.

Ginzberg published more on the economics of race than any other nonblack economist of his time. Many of these publications addressed public policy as it affected racial issues.

Ginzberg published six biographies or autobiographies, including one on his father and one about a man from his father’s hometown, Emanuel Piore, whose wife, Nora Kahn Piore, was a professor of public health economics with Ginzberg at the Columbia School of Public Health.

Ginzberg wrote more about heath economic policy than any other subject. Among his many associates in medical and health economics were Michael M. Davis, Walton H. Hamilton, George H. H. Soule, Hugh Smythe, Roscoe G. Leland, Algie M. Simons, Frank G. Dickinson, Nora Kahn Piore, Eveline M. Burns, and Michael Grossman. He opposed the Clinton health plan of the early 1990s, largely because he thought the president was politically inept in its pursuit.

In 1983, Ginzberg’s separate focus on labor and the nonprofit sector were joined by the Monthly Labor Review in an article containing statistics on the size of the labor force in that sector. This article subsequently was cited by twenty-eight publications.

Because his books and articles generally represented policy and empirical analyses rather than the high mathematical economics favored by most economic journals beginning in the 1950s, he was involved in no professional polemics, and his critics were so few as to be unidentifiable.

GLASNOST

Glasnost is the Russian word for publicity, openness, the state of being public. It refers to a policy of openness in private and public discussions about social, economic, and cultural issues that was initiated by Mikhail Gorbachev.
after his ascension to the leadership of the Union of Soviet Socialist Republics (USSR) in 1985. Gorbachev tried to use open public discussions about the state of the country to generate grassroots political support for his policy of economic restructuring (perestroika) and to outmaneuver his political opponents within the Communist Party. It could be argued that Gorbachev envisioned glasnost as a sort of compensation for the temporary economic hardship that his perestroika program of reforms unavoidably involved.

As a result of the glasnost policy, many sensitive historical issues, such as the brutality of the regime of Joseph Stalin (1879–1953), were acknowledged and the Soviet Union’s “official” history was rewritten. The policy also brought to public attention the economic stagnation in the country and permitted open criticism of government policies. It was one of the main aims of Gorbachev’s glasnost policy to make the state and its entrenched elites accountable to the public by revealing the real economic situation and by allowing the Soviet people to express their wishes. Glasnost destroyed the myth that everyone was happy under the Soviet Union and praised the country’s leadership, but the policy exposed many more fundamental problems than Gorbachev had expected.

It is generally believed that Gorbachev had planned to use the Leninist ideology to thoroughly reform the Soviet Union without destroying it. Nikita Khrushchev (1894–1971), an earlier Soviet leader, tried to reform the USSR using soft methods but was not successful, so Gorbachev may have thought that a policy like glasnost was his only chance to push the necessary economic reforms through. However, freedom of expression unleashed forces that Gorbachev could not control: The media started to aggressively criticize long-denied problems, especially the country’s poor quality of life; revelations about the horrors of the Stalin era undermined Soviet political elites; and Moscow’s grip on the Soviet republics weakened and nationalistic feelings revived. The rapid rise of nationalism and calls for independence in such places as Azerbaijan, Estonia, Georgia, Lithuania, Latvia, and Ukraine were important consequences of glasnost, which allowed and to some degree encouraged people to think about their sovereignty and independence. Thus, glasnost contributed to the eventual demise of the Soviet Union.

Glasnost achieved Gorbachev’s aim of giving people freedom of expression, which before then had been strictly prohibited in the Soviet Union, but undermined his other aims and resulted in the collapse of the Soviet Union in 1991. Although Russia remains a relatively poor country, its citizens now have more freedom than at any other time in Russian and Soviet history. Glasnost also resulted in a renaissance in Soviet cultural and artistic life and in a revival of religion. Previously banned writers became widely read by the general public and new writers and artists emerged. Glasnost has also become one of the few Russian words commonly used in English, which shows the extent of its international influence.

**GLASS CEILING**

The expression *glass ceiling* has been used to describe artificial barriers based on attitudinal or organizational bias that prevent qualified individuals from advancing to positions of power offering higher salaries and more responsibility and authority. Research has shown that, compared to men and whites, women and racial minorities in professional occupations are concentrated in lower- and middle-level positions and are underrepresented in upper managerial ranks. Positive steps have been taken to promote equality of opportunity, ranging from affirmative action legislation to greater diversity in hiring and promotions on the part of employers. Yet, despite these widely publicized efforts, women and minorities still do not enjoy the same advancement opportunities as men and whites. The continued existence of a glass ceiling can be attributed to an interplay of cultural and structural factors.

There are a number of explanations for the existence of a glass ceiling. The concept of *homo social reproduction* suggests that when there is imperfect information on the potential of a candidate, employers or managers generally prefer to hire or promote someone who looks and thinks...
like them. (The questionable assumption underlying this argument is that people with similar gender, racial, or educational backgrounds tend to think and act alike.) This puts women and minorities at a competitive disadvantage, because the majority of decisions regarding hiring and promotion are still made by men/whites.

There is much evidence to suggest that “who you know” (network ties) is as important as “what you know” (education, skills) in moving up the organizational hierarchy. Due to their comparatively recent entry into the labor market, women and minorities still have difficulty in setting up and expanding professional connections. Not being able to tap into the “old boy” network is detrimental to their career progress. To crack the glass ceiling, female and minority workers have had to build up their reputation and gain access to resources through relationships with people with status and authority inside and outside their organization, be they acquaintances, mentors, sponsors, or colleagues. Additionally, female and minority workers are especially vulnerable when they are present in only token numbers. Limited representation increases the pressure on them to perform, heightens their differences from the dominant group, and constrains their roles within the organization. This situation will inevitably improve as the presence of women and minorities increases over time.

Much evidence suggests that a range of discriminatory attitudes make women and minorities less likely to get as far as their male/white counterparts with similar backgrounds. Employers may be reluctant to groom women or racial minorities for leadership positions, owing to stereotypes they hold about members of certain groups as well as their concern about potential bias on the part of customers and male/white workers. Employers tend to view women as less dependable and less career-oriented, because of women’s marriage and family responsibilities. Because of their marginal status in society, women and minorities may have difficulty in commanding respect or obedience from male/white subordinates or in exercising authority in negotiations or confrontations. Furthermore, management and administration have traditionally been considered masculine activities. The queuing theory postulates that discrimination results in a gender/race hierarchy in hiring and promotions. Employers tend to prefer male and white workers to female and minority workers. As a result, men/whites tend to monopolize the most desirable jobs, such as management positions, while women and minorities are relegated to low-paying or less-prestigious positions such as staff or technical work.

The existence of the glass ceiling can result in several outcomes for women and minorities:

1. Title inflation: For window-dressing purposes, firms may promote women and minorities at a relatively high rate to high-profile positions as tokens or glorified managers without conferring any real or additional authority upon them.

2. Job segregation by sex/race: To preserve the existing power structure in an organization and society, employers may place women and minorities in positions or departments that only allow them to supervise female or minority subordinates (e.g., affirmative action or human resource departments).

3. Career changes: The glass ceiling that limits how many women and minorities move up the organizational hierarchy may be a powerful incentive for them to contemplate alternative routes to improved occupational status, such as self-employment or setting up a business where they will be their own boss.

Compounding the cultural and structural factors already discussed, declining opportunities in middle and upper management resulting from corporate downsizing may have intensified competition between and discrimination against women and minorities.

GLAZER, NATHAN
1924–

Formerly professor of Education and Social Structure and now professor emeritus in the Graduate School of Education, Harvard University, Nathan Glazer (1924–) is also the coeditor of The Public Interest, assistant editor of Commentary, and contributing editor to The New Republic. He has been an influential and at times controversial figure in American public life due to his analyses of immigration, affirmative action, race relations, and multiculturalism. Closely associated with New York intellectuals such as Daniel Bell, Glazer was a student follower of Leon Trotsky (1879–1940), the Russian revolutionary. With the economic recovery that followed the Great Depression (1929–1932), Glazer, like many Jewish intellectuals, came to see capitalist America as a successful liberal democracy in which each successive wave of immigrants had been eventually incorporated into society and had benefited from growing economic prosperity. Glazer assumed that Americanization was an unproblematic process, but that optimism has been challenged by the fact that black progress appears to have come to an end in the 1970s. His critics have argued that the ethnic integration he described occurred because immigrants took on the mantle of whiteness in a society where anti-black racism was endemic.

Glazer collaborated with David Riesman on The Lonely Crowd (1950), and his first academic publication, The Social Basis of American Communism, appeared in 1961. However, Glazer first attracted academic attention through his publications on race and ethnicity, such as American Judaism (1957) and his collaborations with Daniel Moynihan (1927–2003), Beyond the Melting Pot (1963) and Ethnicity: Theory and Practice (1975). Various articles on these topics appeared as Ethnic Dilemmas, 1964–1982 (1983).

An early critic of Great Society programs, Glazer has emerged as an influential figure in American politics, opposing affirmative-action programs in support of black Americans. In Affirmative Discrimination (1975)—a collection of essays dating back to the early 1970s—Glazer claimed that the apparent failure of black Americans to achieve assimilation and social mobility in an affluent American society was the result of fragmented families, declining inner-city schools, and disorganized communities. Glazer concluded that the main problem in the United States was not systematic racism, but employment discrimination against blacks. In Beyond the Melting Pot, Glazer and Moynihan argued that it is because black Americans have suffered profoundly from the effects of slavery that they have not experienced the upward social mobility enjoyed by many ethnic minorities. Repairing this deep-seated historical problem of black Americans was beyond the capacity of social policies. Glazer has therefore been one of the main proponents of the black dysfunctionality hypothesis that has been embraced by Daniel Moynihan, Edward Banfield, and Richard Herrnstein, and his arguments against affirmative action policies were significant in the growth of neoconservatism in American public life. Critics such as Stephen Steinberg (see Steinberg’s Turning Back: The Retreat from Racial Justice in American Thought and Policy, 1995) have argued that Glazer’s policy prescriptions amount to blaming the victim.

Glazer has also been influential in the movement against liberal policies in multicultural school curricula. In We Are All Multiculturalists Now (1997) and Sovereignty under Challenge (2002) he claims that a multicultural education compromises historical truth and erodes national unity through the “Balkanization” of the American republic. Glazer himself rejects the neoconservative label and has been critical of small groups whose veto power keeps controversial subjects out of the school curricula, thereby, in his estimation, creating a bland, unreal America.

GLOBAL WARMING

Understanding the causes of and responses to global warming requires interdisciplinary cooperation between social and natural scientists. The theory behind global warming has been understood by climatologists since at least the 1980s, but only in the new millennium, with an apparent tipping point in 2005, has the mounting empirical evidence convinced most doubters, politicians, and the general public as well as growing sections of business that global warming caused by human action is occurring.

DEFINITION OF GLOBAL WARMING

Global warming is understood to result from an overall, long-term increase in the retention of the sun’s heat around Earth due to blanketing by “greenhouse gases,” especially CO₂ and methane. Emissions of CO₂ have been rising at a speed unprecedented in human history, due to accelerating fossil fuel burning that began in the Industrial Revolution.
Global Warming

The effects of the resulting “climate change” are uneven and can even produce localized cooling (if warm currents change direction). The climate change may also initiate positive feedback in which the initial impact is further enhanced by its own effects, for example if melting ice reduces the reflective properties of white surfaces (the “albedo” effect) or if melting tundra releases frozen methane, leading to further warming. Debate continues about which manifestations are due to long-term climate change and which to normal climate variability.

SPEEDING UP THE PROCESS

Global warming involves an unprecedented speeding up of the rate of change in natural processes, which now converges with the (previously much faster) rate of change in human societies, leading to a crisis of adaptation. Most authoritative scientific bodies predict that on present trends a point of no return could come within ten years, and that the world needs to cut emissions by 50 percent by mid twenty-first century.

It was natural scientists who first discovered and raised global warming as a political problem. This makes many of the global warming concerns unique. “Science becomes the author of issues that dominate the political agenda and become the sources of political conflict” (Stehr 2001, p. 85). Perhaps for this reason, many social scientists, particularly sociologists, wary of trusting the truth claims of natural science but knowing themselves lacking the expertise to judge their validity, have avoided saying much about global warming and its possible consequences. Even sociologists such as Ulrich Beck and Anthony Giddens, who see “risk” as a key attribute of advanced modernity, have said little about climate change.

For practical purposes, it can no longer be assumed that nature is a stable, well understood, background constant and thus social scientists do not need direct knowledge about its changes. Any discussion of likely social, economic, and political futures will have to heed what natural scientists say about the likely impacts of climate change.

GROWING EVIDENCE OF GLOBAL WARMING

While originally eccentric, global warming was placed firmly on the agenda in 1985, at a conference in Austria of eighty-nine climate researchers participating as individuals from twenty-three countries. The researchers forecast substantial warming, unambiguously attributable to human activities.

Since that conference the researchers’ position has guided targeted empirical research, leading to supporting (and increasingly dire) evidence, resolving anomalies and winning near unanimous peer endorsement. Skeptics have been confounded and reduced to a handful, some discredited by revelations of dubious funding from fossil fuel industries.

Just before the end of the twentieth century, American researchers released ice-thickness data, gathered by nuclear submarines. The data showed that over the previous forty years the ice depth in all regions of the Arctic Ocean had declined by approximately 40 percent.

Five yearly aerial photographs show the ice cover on the Arctic Ocean at a record low, with a loss of 50 cubic kilometers annually and glacier retreat doubling to 12 kilometers a year. In September 2005 the National Aeronautics and Space Administration (NASA) doubled its estimates of the volume of melted fresh water flowing into the North Atlantic, reducing salinity and thus potentially threatening the conveyor that drives the Gulf Stream. Temperate mussels have been found in Arctic waters, and news broadcasts in 2005 and 2006 have repeatedly shown scenes of Inuit and polar bears (recently listed as endangered) cut off from their hunting grounds as the ice bridges melt.

In 2001 the Intergovernmental Panel on Climate Change (IPCC), the United Nation’s scientific panel on climate change, had predicted that Antarctica would not contribute significantly to sea level rise this century. The massive west Antarctic ice sheet was assumed to be stable. However, in June 2005 a British Antarctic survey reported measurements of the glaciers on this ice sheet shrinking. In October 2005 glaciologists reported that the edges of the Antarctic ice sheets were crumbling at an unprecedented rate and, in one area, glaciers were discharging ice three times faster than a decade earlier.

In 2005 an eight-year European study drilling Antarctic ice cores to measure the past composition of the atmosphere reported that CO2 levels were at least 30 percent higher than at any time in the last 65,000 years. The speed of the rise in CO2 was unprecedented, from 280 parts per million (ppm) before the Industrial Revolution to 388 ppm in 2006. Early in 2007 the Norwegian Polar Institute reported acceleration to a new level of 390 ppm. In January 2006 a British Antarctic survey, analyzing CO2 in crevase ice in the Antarctic Peninsula, found levels of CO2 higher than at any time in the previous 800,000 years.

In April 2005 a NASA Goddard Institute oceanic study reported that the earth was holding on to more solar energy than it was emitting into space. The Institute’s director said: “This energy imbalance is the ‘smoking gun’ that we have been looking for” (Columbia 2005).

The second IPCC report in 1996 had predicted a maximum temperature rise of 3.5 degrees Fahrenheit by the end of the twenty-first century. The third report, in 2001, predicted a maximum rise of 5.8 degrees Fahrenheit by the end
of the twenty-first century. In October 2006 Austrian glaciologists reported in *Geophysical Research Letters* (Kaser et al.) that almost all the world’s glaciers had been shrinking since the 1940s, and the shrinking rate had increased since 2001. None of the glaciers (contrary to skeptics) was growing. Melting glaciers could pose threats to the water supply of major South American cities and is already manifest in the appearance of many new lakes in Bhutan.

In January 2007 global average land and sea temperatures were the highest ever recorded for this month; in February 2007 the IPCC Fourth Report, expressing greater certainty and worse fears than the previous one, made headlines around the world. In 1995 few scientists believed the effects of global warming were already manifest, but by 2005 few scientists doubted it and in 2007 few politicians were willing to appear skeptical.

Although rising temperatures; melting tundra, ice and glaciers; droughts; extreme storms; stressed coral reefs; changing geographical range of plants, animals, and diseases; and sinking atolls may conceivably all be results of many temporary climate variations, their cumulative impact is hard to refute.

**ANOMALIES AND REFUTATIONS**

The science of global warming has progressed through tackling anomalies cited by skeptics. Critics of global warming made attempts to discredit the methodology of climatologist Michael Mann’s famous “Hockey stick” graph (first published in *Nature* in 1998). Mann’s graph showed average global temperatures over the last 1,000 years, with little variation for the first 900 and a sharp rise in the last century. After more than a dozen replication studies, some using different statistical techniques and different combinations of proxy records (indirect measures of past temperatures such as ice cores or tree rings), Mann’s results were vindicated. A report in 2006 by the U.S. National Academy of Sciences, National Research Council, supported much of Mann’s image of global warming history. “There is sufficient evidence from the tree rings, boreholes, retracing glaciers and other ‘proxies’ of past surface temperatures to say with a high level of confidence that the last few decades of the twentieth century were warmer than any comparable period for the last 400 years.” For periods before 1600, the 2006 report found there was not enough reliable data to be sure but the committee found the “Mann team’s conclusion that warming in the last few decades of the twentieth century was unprecedented over the last 1,000 years to be plausible” (National Academy of Science press release 2006).

Measurements from satellites and balloons in the lower troposphere have until recently indicated cooling, which contradicted measurements from the surface and the upper troposphere. In August 2005 a publication in *Science* of the findings of three independent studies described their measurements as “nails in the coffin” of the skeptics’ case. These showed that faulty data, which failed to allow for satellite drift, lay behind the apparent anomaly.

Another anomaly was that observed temperature rises were in fact less than the modelling of CO₂ impacts predicted. This is now explained by evidence on the temporary masking properties of aerosols, from rising pollution and a cyclical upward swing of volcanic eruptions since 1960.

Critics of global warming have been disarmed and discredited. Media investigations and social research have increasingly highlighted the industry funding of skeptics and their think tanks, and the political pressures on government scientists to keep silent. Estimates of the catastrophic costs of action on emissions have also been contradicted most dramatically by the British Stern Report in October 2006. Many companies have been abandoning the skeptical business coalitions. The Australian Business Round Table on Climate Change estimated in 2005 that the cost to gross domestic product of strong early action would be minimal and would create jobs.

**SCIENTIFIC CONSENSUS**

In May 2001 sixteen of the world’s national academies of science issued a statement, confirming that the IPCC should be seen as the world’s most reliable source of scientific information on climate change, endorsing its conclusions and stating that doubts about the conclusions were not justified.

In July 2005 the heads of eleven influential national science academies (from Brazil, Canada, China, France, Germany, India, Italy, Japan, Russia, the United Kingdom, and the United States) wrote to the G8 leaders warning that global climate change was “a clear and increasing threat” and that they must act immediately. They outlined strong and long-term evidence “from direct measurements of rising surface air temperatures and subsurface ocean temperatures and from phenomena such as increases in average global sea levels, retreating glaciers and changes to many physical and biological systems” (Joint Science Academies Statement 2005).

There are many unknowns regarding global warming, particularly those dependent on human choices; yet the consequences for society of either inadequate action or of any effective responses (through reduced consumption or enforced and subsidized technological change) will be huge. It is, for example, unlikely that the practices and values of free markets, individualism, diversity, and choice will not be significantly modified either by economic and political breakdowns or alternatively by the radical measures needed to preempt them.
INADEQUATE ACTION AND NEEDED TRANSFORMATIONS

Kyoto targets are at best a useful first step. However, even these targets, which seek to peg back emissions to 1990 levels by 2010, are unlikely to be met. World CO$_2$ emissions in 2004 continued to rise in all regions of the world, by another 4.5 percent, to a level 26 percent higher than in 1990. A rise of over 2 degrees is considered inevitable if CO$_2$ concentrations pass 400 ppm. At current growing emission rates, the concentration would reach 700 ppm by the end of the twenty-first century. The continuing industrialization of China, recently joined by India, points to the possibility of even faster rises than these projections indicate.

If unpredictable, amplifying feedback loops are triggered, improbable catastrophes become more likely. The Gulf Stream flow could be halted, freezing Britain and Northern Europe. Droughts could wipe out the agriculture of Africa and Australia, as well as Asia, where millions depend on Himalayan melt water and monsoon rains. If the ice caps melt completely over the next centuries, seas could rise by 7 meters, devastating all coastal cities. Will the human response to widespread ecological disasters give rise to solidarity and collective action, such as the aid that came after the 2004 Asian Tsunami or to social breakdowns, as seen in New Orleans after 2005’s Hurricane Katrina and in the Rwandan genocide?

Social and technical changes with the scale and speed required are not unprecedented. The displacement of horsepower by automobiles, for example, was meteoric. Production of vehicles in the United States increased from 8,000 in 1900 to nearly a million by 1912. Substantial regulation or differential taxation and subsidies would be indispensable to overcome short term profit motives and free riding dilemmas (where some evade their share of the cost of collective goods from which they benefit). Gains in auto efficiency in the 1980s, for example, were rapidly reversed by a new fashion for sport utility vehicles.

The debates that have emerged in the early twenty-first century have been related to responses, with different winners and losers, costs, benefits, dangers, and time scales for each response. Advocates of reduced energy consumption or increased efficiency, or energy generation by solar, wind, tidal, hydro, biomass, geothermal, nuclear, or clean coal and geo-sequestration, argue often cacophonously. Yet it seems probable that all these options are needed.

It will be essential for social and natural scientists to learn to cooperate in understanding and preempting the potentially catastrophic collision of nature and society. In order to accomplish this, market mechanisms; technological innovation; international, national, and local regulations; and cultural change will all be needed. Agents of change include governments, nongovernmental organizations, and public opinion, but the most likely front-runner might be sectors of capital seeking profit by retooling the energy and transport systems, while able to mobilize political enforcement.

GLOBALIZATION, ANTHROPOLOGICAL ASPECTS OF

In popular and scholarly discourse, the term globalization is widely used to put a name to the shape of the contemporary world. In the realms of advertising, policy making,
politics, academia, and everyday talk, globalization refers to the sense that we are now living in a deeply and increasingly interconnected, mobile, and sped up world that is unprecedented, fueled by technological innovations and geopolitical and economic transformations. As a way to name our contemporary moment, the term globalization entered popular media and advertising in the early 1990s (Tsing 2000). After the fall of the Berlin Wall in 1989 and the breakup of the Soviet Union, enthusiasm accelerated for increasing international trade, deregulating national economies, privatizing the state, structurally adjusting developing-world economies, and increasing the transnationalization of corporations. Globalization was the new term that signaled this triumph of the capitalist market. As social science became increasingly focused on globalization, theories of globalization emphasized the transformations in labor, capital, state, and technology that have created a heightened sense of global interconnection or what has been called by the geographer David Harvey “time-space compression” (Harvey 1989).

As globalization has become a dominant narrative of our times, it also has become so for the discipline of anthropology, where it is both a specific object of methodological and theoretical reflection and one of the dominant horizons for a wide variety of scholarship. It became an increasingly central preoccupation at a time when the discipline was in crisis, both methodologically and theoretically. Anthropological attempts to grapple with globalization were crucial for reworking the anthropological concept of culture and for reconfiguring ethnographic methodology. In so doing, the anthropology of globalization has expanded and nuanced dominant theories of globalization while raising questions about its effects, scope, and reach.

Dominant theories of globalization are, more often than not, macrosociological, emphasizing large-scale perspectives on economic, political, and cultural transformations that are understood to either fuel or be the effects of globalization. One of the key contributions of the anthropology of globalization has been to emphasize the interconnection between what is called the “local” and the “global,” emphasizing the interplay between large-scale global transformations and the realities of long-standing social and cultural worlds. An attention to this interplay has led to a focus on mapping and naming the large-scale shifts in culture and political economy that constitute globalization—something that characterizes much literature on globalization across the social sciences—but also a focus on people’s everyday lived experiences and their transformations under conditions of globalization.

While the local-global framework of analysis shifted the macro, horizontal view of dominant theories of globalization, it also contributed to rethinking the conventional scales of ethnographic analysis. By the late 1980s the highly localized, isolated, and holistic frameworks that characterized ethnographic methodology, which is often divorced from attention to larger power structures and cultural interactions, had come under scrutiny. Whereas the anthropology of globalization emphasized the local in the face of assertions about the dominance and power of large-scale global processes, within the discipline itself contextualizing the local within the global was a key way anthropology began to shift its own frameworks for understanding the productions of culture and meaning within the contemporary world. This has led to new ways of thinking about ethnography beyond a focus on the purely place-based, local context, ones that emphasize multistited ethnography, ethnography across social scales, and ethnographies of networks, among others.

The framework of the local-global goes along with a central focus on the cultural dimensions of globalization. Dominant theories of globalization understand it as a primarily economic and political process. If these theories do not pay attention to the cultural dimensions of globalization, it is often to argue that economic and political transformations that underlie globalization lead to cultural homogenization, often understood as “Americanization.” This thesis is often rendered in terms of the cultural consequences of dominant U.S. commodity exports such as McDonald’s and U.S. television programs. The anthropology of globalization, in particular the work of Arjun Appadurai, has argued that globalization is not a monolithic U.S. export but rather a “disjunctive,” heterogeneous process with multiple centers of influence and interaction (Appadurai 1996). Further, culture is not simply derivative of economy and politics. The emphasis on people’s experiences, lived realities, and what Appadurai calls the “social imaginary” has led to an emphasis on notions of agency and resistance in the face of large-scale global processes and transformations, ones that create cultural worlds that overlap but are not simply derivative of dominant capital and labor “flows.” This has led to an emphasis on heterogeneous, multiple, and varied cultural responses to globalization, ones that emphasize the production of meaning within localized contexts.

An emphasis on the cultural dimensions of globalization has complicated theories of globalization focused on economy and politics, but it also has been central to transforming the anthropological concept of culture. The critique of ethnography in the late 1980s went hand in hand with a rethinking of the culture concept, which was also understood to be overly holistic, consensual, isolated, and divorced from power. Examining the productions of culture within a global framework that emphasizes everyday life as it interacts with the increasing importance of mass media and migration, among other factors, has challenged the ways anthropology has assumed the isomorphism
between place and culture. The anthropology of globalization has paid significant attention to the deterritorialization of culture, which has led to a more mobile and dynamic sense of cultural production.

Anthropological scholarship on globalization is vast and varied. Ethnographies of labor, work, and capital have examined inequality and opportunity within free-trade zones and under new conditions of migration, focusing on issues of gender, generation, and class. A significant body of work has explored the experiences of migrants, particularly on identity formation and nationalism within various diasporic and transnational communities. Another important area of research has explored the impact of new consumer and commodity regimes, and significant attention has been paid to the effects and experiences of new media and other technologies on various axes of identity formation, including gender, youth, class, and nation. Increasing attention is also being paid to the effects of globalization on social movements, politics, and community organizing. Finally, significant work has examined the role of the state and transformations in nation-state formation in the context of globalization.

Although the conceptualization of “local-global” has been instrumental in challenging overly homogenizing and macrosociological views of globalization, it sometimes has produced an overly romanticized and simplistic view of the local as a space of resistance and authenticity. The anthropology of globalization continues to produce dynamic work that refines and complicates our sense of what constitutes the local, with attention to the intersection between history and culture at multiple scales that include the local, regional, and national as they crisscross each other in and through transnational interactions. A key challenge for the anthropology of globalization is in maintaining its assumption of the global as the space of homogeneity while arguing against this homogeneity through locating particularity and difference within the realm of the local. Contemporary work in the anthropology of globalization is complicating our sense of what constitutes the global, emphasizing the productions of locality within global capitalism and demonstrating the ways the global itself is not some abstract set of large-scale social processes; instead, it has its own particularities that can be tracked and named (Tsing 2000). Finally, anthropology continues to debate and explore what has been called the "abjection" of globalization (Ferguson 2002). The question of whether globalization is a good or a bad thing, particularly for the world’s poor, has been a subject of popular and political struggles that has fueled a worldwide antiglobalization movement. Anthropology has emphasized both the cultural resilience and creativity of local populations under conditions of globalization while recognizing new conditions and structures of exploitation and vulnerability. Although some argue that there is no singular notion of globalization that can be termed “good” or “bad”—only an altered terrain of struggle and hope in different arenas—others seek to track, in multiple ways, structures of expanding opportunity or greater exploitation under conditions of globalization.

GLOBALIZATION, SOCIAL AND ECONOMIC ASPECTS OF

Since the 1970s and 1980s, the increasing intensity of international economic exchange, the rising prominence and influence of international organizations, the diffusion of cultural products across national boundaries, the spanning of social ties across international borders, and global environmental problems have all placed globalization prominently on the agenda of social science. The definition of globalization remains contested, but globalization can be conceptualized as a multidimensional process of international network formation. (Globalization could also be understood as an ideology, but this would more accurately be termed globalism.) The network metaphor clarifies the concept of globalization by highlighting both the nodes (e.g., people, organizations, and states) and the relations (e.g., trade, investment, organization membership, consumption, and migration) that are central to the globalization process. Thinking about globalization as multidimensional network formation is also a useful heuristic for understanding the established facts and unresolved debates surrounding the phenomenon. Moreover,
it helps differentiate the multiple levels of analysis inherent in the process: globalization involves local, regional, national, international, and world levels of social life.

Below, this entry employs the network heuristic to discuss the central issues in the social science of globalization. The discussion begins by exploring relatively settled terrain: the multiple dimensions of globalization. From there, the entry moves to rockier ground: the questions of whether globalization is really new, how extensive it is, and precisely what effects it has.

**FIVE DIMENSIONS OF GLOBALIZATION**

Cross-national connections are created in the economic, political, cultural, social, and environmental domains. Although these dimensions necessarily overlap, it is analytically useful to distinguish them. Economic globalization results when corporations go multinational, either by selling their products in other countries, buying corporations located in foreign countries, or opening branch offices or subsidiaries outside their home country. Multinational corporate expansion, and the consumption of foreign-sourced goods and services, aggregate into exports, imports, and investment relations among national economies. Political globalization, or the formation of international connections among elected officials, bureaucrats, judges, social movement activists, and states, has also generated intense interest. Political globalization results in part through the formation of intergovernmental organizations (IGOs) like the United Nations and the World Trade Organization, and international nongovernmental organizations (INGOs) like the International Committee of the Red Cross. For instance, Anne-Marie Slaughter (2004) shows how political officials, especially regulators and judges, weave a web of global governance and “world order” through international ties formed by these organizations.

In the cultural field, the major world religions, media conglomerates, multinational corporations, and international tourism transmit and translate meaning (embedded in faith traditions, ideas, products, and practices) and symbols across international boundaries. The development of the international communication infrastructure (radio, satellites, intercontinental telecommunication cables) and the rapid expansion of communication technologies (Internet, cell phones, television) foster this process. Closely related is social globalization, or transnational connections formed by mobile individuals as they create social relationships. For instance, the density of international ties across countries grows as migrants maintain connections to their origin countries (e.g., through remitting money back home) while building new relationships in their destination countries (e.g., through work, community, and family).

Many identify the environment as a fifth dimension of globalization. If nations are the nodes in international networks, then environmental problems create connections by crossing borders: global warming, ozone depletion, and acid rain have all been defined by social movement activists and scientists as international problems that require international solutions. Indeed, environmental problems illustrate how the various dimensions of globalization sometimes reinforce one another: social movement activists bind together through international social movement organizations (social globalization) to spread awareness of environmental problems (cultural globalization) caused in part by multinational corporations (economic globalization), and urge the adoption of international agreements like the 1997 Kyoto Protocol on greenhouse gas emissions (political globalization).

**WHEN AND WHERE IS GLOBALIZATION?**

While the example of the Kyoto Protocol illustrates how the dimensions of globalization can cohere, intense international debate over the protocol raises questions about the pace and periodization of globalization, and, more fundamentally, about how “global” globalization is. Indeed, debate over the timing and extent of globalization animates much research. For instance, world-systems theorists such as Immanuel Wallerstein and Christopher Chase-Dunn trace the millennia-long evolution of international economic and political systems, and world-society theorists such as John Meyer and John Boli view social and cultural globalization through a long historical lens that looks back over a century. Social scientists have not reached consensus on when globalization in its various forms began, but there is an emerging consensus that the world has experienced a renewed and possibly distinct economic globalization since the mid-1970s (i.e., after the oil crises and the collapse of the Bretton Woods system of fixed exchange rates in 1973). Only during this period did the level of international trade surpass its previous peak in the early twentieth century. Thus, economic globalization may follow waves, with crests of integration followed by troughs of separation.

In the political dimension, there is also evidence that globalization substantially intensified in the latter half of the twentieth century. With the establishment of the United Nations and related IGOs (including the International Monetary Fund, World Bank Group, International Labour Organization, and World Health Organization), a global governance framework emerged. It has fostered the creation of thousands of intergovernmental and nongovernmental organizations that generate a network of international association (Boli and Thomas 1999). Key nodes in this network include regional orga-
Globalization, Social and Economic Aspects of

Organizations like the European Union (EU) that liberalize trade and create common policies among nations within negotiated geographical boundaries. The EU has progressed furthest toward the creation of a regional market and government, as it has allowed the free movement of people across borders, eliminated barriers to trade, created a supranational court, and established supranational policies. The EU, established as the European Economic Community in 1957, may have inspired regional integration efforts in other parts of the world, including Southeast Asia—the Association of Southeast Asian Nations (ASEAN, 1967); South America—Mercado Común del Sur (Southern Common Market or Mercosur, 1991); North America—the North American Free Trade Agreement (NAFTA, 1994); Central America—the Central American Common Market (CACM, 1960); and Africa—the Organization of African Unity (OAU, 1963). These organizations may transform world politics by changing how states interact and by generating new layers of policy and politics.

The accelerating economic liberalization and polity construction within geographical regions fuels the debate over where globalization actually happens (indeed, a large literature addresses whether regional integration creates “stepping-stones” or “stumbling blocks” to a fully integrated global system). Here again, the network heuristic helps. Some images of globalization depict a world where national nodes worldwide are increasingly interconnected without regard to place, while others allow for a more fragmented and uneven network where some nodes are linked much more densely than others. These contrasting images manifest in research that has shown, for instance, that Western Europe is much more densely intertwined in both the economic and political dimensions than nations in other world regions.

**WHAT DOES GLOBALIZATION DO?**

Setting aside controversies of period and place, social scientists blame or credit globalization for a panoply of social ills and goods, from economic inequality to economic growth, from political domination to democratization, from the decline of national sovereignty to the renaissance of the state, from social engagement to xenophobia, and from cultural homogenization to ethnic conflict. Meanwhile, others see a feeble globalization. Here, this entry reviews some of the key arguments for what globalization does.

Globalization, advanced partly by IGOs like the World Trade Organization and the International Monetary Fund that compel economic liberalization, has been the subject of vigorous debate about growing income gaps between rich and poor. The argument is that, in the name of international competitiveness, government revenue and expenditures are cut, and industries are deregulated and privatized. Globalization is also blamed for lowering the wages of less-skilled workers by shifting manufacturing jobs to lower-wage countries, and by enlarging the pool of low-wage labor through immigration. In turn, in low-wage countries of the “Global South,” globalization is blamed for proliferating sweatshops owned by multinational corporations, producing an underclass of nonunionized labor, and generating an exploitive transnational capitalist and entrepreneurial class. Moving from individuals to countries, globalization arguably benefits rich countries at the expense of poor countries, by further concentrating wealth in rich countries as profits are repatriated from the Global South to the Global North. On the other hand, much of the literature has been skeptical of the criticisms that have been leveled at globalization. Just to take one example of the potentially salutary effects of globalization, it has been argued that globalization actually reduces disparities among rich and poor countries in their overall levels of economic development, by spreading industrialization to poor countries.

Social scientists also disagree intensely over whether globalization brings about political convergence among states. There is evidence that states adopt increasingly similar policies in areas such as education, welfare, the environment, human rights, and population as they interact more with international organizations. International organizations, it is argued, create and diffuse policy models (or “scripts”) to states, and states adopt these models, in part, to appear as legitimate members of a world society. This process may reflect the spread of modern, Western culture (e.g., individualism, universalism, rationalism, science, and progress) around the globe. These claims remain controversial, and some argue that international organizations serve national interests and as such have strictly limited independent influence. It is a major challenge to contemporary social science to bring some resolution to the varied, contradictory, and multivalent picture of globalization that has emerged.

**BIBLIOGRAPHY**

Discredited today and largely ignored by his compatriots during his lifetime, Comte Joseph Arthur de Gobineau was nonetheless a key contributor to nineteenth-century race theories. Born in Ville-d’Avray, France, in 1814, he argued that racial difference was not only key to understanding the problems of history, but that it was the precondition of history. Comte de Gobineau posited two broad categories based on the shape of people’s heads: Aryan or dolichocephalic populations, and Alpine or brachycephalic people. But it was his theory of racial mixing and degeneracy that won him admirers and detractors.

In the Essai sur l’inégalité des races humaines (Essay on the Inequality of the Human Races, 1853–1855), Gobineau claims the existence of three original, distinct human races: white, black, and yellow. Of these, white people, or Aryans, occupied the highest rank in a hierarchy of three. However, the “fusion” of these original races in history had, Gobineau argues, resulted in degeneracy and would eventually account for the decline of all civilization. The Essai and other writings, such as La fleur d’or (The Golden Flower) which was published posthumously in Germany in 1918 and in France in 1923, are thus infused with apocalyptic inferences: despite notable exceptions of “golden” flowering, all human societies face decline, not because of corruption or the abandonment of religious ideals, or even because of bad government. In themselves, these factors—“poisonous blossoms”—cannot undermine a nation unless its people had already degenerated through mixing. The “degenerate” man properly so-called is racially different from “the heroes of the great ages” who, for example, were to be found in the Roman Empire prior to its greatest successes. Despite his French nationality, Gobineau’s Martinican Creole mother took him to Germany and had him educated in the gymnasium system, where he acquired his admiration for things Germanic. He came to believe that the Germanic race was heir to Roman purity, and he dedicated his Essai to George V (1819–1878), king of Hanover.

Although a protégé of Alexis de Tocqueville (1805–1859), through whom he received his first diplomatic postings in Persia, Gobineau eschewed Enlightenment notions of intellectual equality or fraternity across different races. Tocqueville labeled Gobineau’s views false and pernicious. In turn, Gobineau claimed that intellectual fraternity across races was the deluded product of miscegenation. This was the risk of imperialism. According to Gobineau, a “principle of death” emerges when a stronger people assumes ownership over conquered lands. Although growing into nationhood, such societies faced the danger of “mixing” their blood. Despite producing an initial strength, these newly mixed people would lack the power of their ancestors. Segregation was thus natural and manifested itself in a “spirit of isolation” that persists in peoples despite their mixed origins. In his broad-sweeping claims, he praises Arabs, Persians, Jews, Farsis, and Turks for being “repulsed” by the prospect of “crossing” blood.

Gobineau’s elevation of a blond, blue-eyed Aryanism as the racial ideal found acceptance in Imperial Germany, attracting the admiration of Richard Wagner (1813–1883), Ludwig Schemann (1852–1938), and Chancellor Bernhard von Bulow (1849–1929). With von Bulow’s support, Schemann founded the Gobineau Society in 1894. Members included Swiss jurist Johann Kaspar Bluntschli (1808–1881) and British-born political philosopher and proponent of the theory of a German master race, Houston Swiss Chamberlain (1855–1927). Under the sway of Gobineau’s writings, Chamberlain argued for social practices that reflected the inequality of
the races. Chamberlain, however, adjusted Gobineau's theory of degeneracy and predicted instead a growing “Aryan” strength. Gobineau’s influence upon German National Socialism would eventually be incorporated, along with a racialized reading of Charles Darwin (1809–1882), into the pro-Nordic writings of Ludwig Woltmann (1871–1907). In the United States, Gobineau’s *Essai* was translated by Swiss immigrant Henry Hotz, with an appendix by the proslavery physician and polygenist, Josiah Nott (1804–1873). Gobineau was not pleased with the American translation of his *Essai sur l’intégralité des races humaines*, which he thought too selective. Where the original edition ran to over one thousand pages, the American translation was cut down to less than four hundred pages.

What Chamberlain, supporter Robert Knox, and others failed to acknowledge was Gobineau's insistence that the Aryan ideal had been overtaken by history. They also overlooked Gobineau's less than flattering condemnation of white Americans as “an assortment of the most degenerate races of olden-day Europe,” as well as his resistance to American treatment of slaves and Native Americans, and his argument that racial mixing, and specifically black blood, had produced artistic mastery.

Within fifty years of his death, a systematic challenge to and rejection of Gobineau's work had emerged in the writings of Léopold Senghor (1906–2001), Aimé Césaire, and Léon Damas (1912–1978). Their formulation of the *negritude* movement in Paris in the 1930s to 1940s owed much to Senghor's opposition to Gobineau's pronouncements upon race mixing. Senghor's rethinking of Gobineau's work led to his influential theory of cultural *métissage*, an alternative energized multiplicity that incorporated an African past into a hybridized present in the Americas and Caribbean. Among the African diasporic writers influenced by *negritude* was Martinican essayist Suzanne Roussy Césaire (1915–1966). Her call to “cannibalize” and incorporate white Western culture into African diasporic culture reflected the strong cultural backlash against Gobineau's purist agenda.

GOFFMAN, ERVING
1922–1983
Perhaps the most colorful of American sociologists, Erving Goffman, born in Alberta, Canada, led the turn to the micro-sociology of everyday life. He received a PhD in 1953 from the University of Chicago. Goffman’s program began as a development of the work of the French sociologist Émile Durkheim, which set out to uncover the moral order that makes society possible. Where his predecessors, the British social anthropologists, analyzed religious rituals in tribal societies, Goffman examined the secular rituals of modern social interaction. He believed that such rituals construct the modern self, which he studied by examining the conditions in which it is threatened or blatantly manipulated. Goffman analyzed abnormal situations and institutions, including mental hospitals, confidence games, gambling, spying, and embarrassment in social encounters, to reveal the social conditions upholding conventional realities.

In *The Presentation of Self in Everyday Life* (1959), Goffman analyzed social life as a theater, divided into frontstage regions, where official definitions of reality are presented, and backstage regions, where dirty work is hidden and performances are prepared. Privileged occupations and social classes dominate frontstages and present idealized images of selves and institutions, whereas subordinated persons do much of their work backstage and are dominated by frontstage performers.

In *Asylums* (1961) and *Stigma* (1963), Goffman analyzed the extreme backstages of society, such as the schizophrenic wards of mental hospitals. Proposing the concept of “total institutions” for places where all aspects of life are subject to all-encompassing authority that allows no private backstages for the individual, Goffman argued that patients and other inmates engage in resistance through bizarre behavior aimed at supporting a sense of self beyond institutional controls. Thus, the official social processing of persons as deviant tends to promote still further deviance.

Mental illness, in Goffman’s view, is not a characteristic of the individual so much as a social enactment, a spiral of violations of the ritual proprieties of everyday life. In *Behavior in Public Places* (1963) and *Relations in Public* (1971), Goffman made use of the violations exhibited by mental patients, as well as close ethnographic studies of pedestrian traffic and sociable gatherings, to develop a taxonomy of social situations and their tacit requirements and constraints. Unfocused interaction among persons in each others’ physical presence involves tacit monitoring and signals indicating a respect for personal space. Focused interaction carries implications of memberships in groups, however small or temporary, and involves devices for entry and exit into the focus of attention, as well as for guarding boundaries of intimacy and warding off offenses that violate respect for the relationship. In “On Face-Work” (1955) and “The Nature of Deference and Demeanor” (1956), and in *Interaction Ritual* (1967), Goffman applied the theories of Durkheim and Alfred Radcliffe-Brown to the polite ceremonies of greetings, departures, and conversation. The everyday situation is constructed out of efforts at ritual enactment, and the modern individual self is elevated into a Durkheimian sacred object—much as the tribal gods were situationally re-created by the worship of them—through deference given in everyday rituals. There is therefore no essential self, but only an ongoing social construction.

Although Goffman did not contextualize his observations historically, his work casts light on the prestigious pattern of the self in the late twentieth century. Goffman introduced the concept of “role-distance” (in *Encounters*, 1961), in which the actor claims superior sophistication by displaying signs of detachment from the demands of the social role. Games and entertainment, which take up an increasing portion of “postmodernity,” were seen by Goffman as producing a sense of “fun” and excitement by requiring the actor to display engagement in an activity bracketed from ordinary mundane reality, while alsocourting risks that allow a display of “coolness.”

The ritualism of everyday encounters allows some actors to manipulate situations, engage in face-work contests to subtly embarrass others, or deceive them for criminal, business, or political purposes. These analyses have led some theorists to conclude that Goffman viewed the world as a Machiavellian contest of false reality-constructions. But Goffman argued that the social order is basically accommodative, and that situations involve ritual constraints that must be largely respected if any social reality is to be constructed at all. In *Strategic Interaction* (1969), he analyzed espionage and other self-interested manipulations of impressions, concluding that such behavior is limited by the inherent difficulties of sustaining complex deception. Social conflict and domination are possible only when placed upon the background of ritual solidarity enacted in most social encounters.
Goffman’s later works, *Frame Analysis* (1974) and *Forms of Talk* (1981), take up the social construction of multiple social realities. Goffman adopted a moderate position, holding that complex social frames or definitions of reality are built up hierarchically, by bracketing or transforming activity at more basic levels of bodily action, human ecology, and social rituals. Highly laminated social meanings emerge situationally. For example, individuals (1) may make ironic backstage comments (2) during a rehearsal (3) for a commemoration of (4) a historical event, but if a fire breaks out during the rehearsal, all four levels are collapsed to the lowest level of framing, the fire.

Language itself is built up through a hierarchy of framing devices. Talk is a move in the interaction ritual through which social membership is negotiated. It is built upon prior enactments and constrained by the framing or stage-work necessary to sustain or transform the current situational definition. Social reality, self, and language are all emergent phenomena, built out of the ritual constraints of the interaction order. Goffman died in 1983 in Philadelphia, Pennsylvania.

**GOING NATIVE**

The phenomenon of going native is one of the less commonly known outgrowths of European colonialism. It emerged as a result of the meeting of European and indigenous cultures and drew its strength from the perceived differences between those cultures. The term refers to the desire of non-aboriginals to identify with and immerse themselves in native culture.

In North America, cultural conversions of this type have taken a variety of forms. During the sixteenth and seventeenth centuries, Europeans intent on survival in an unfamiliar terrain were wise to adopt aspects of aboriginal lifestyles in matters ranging from food and clothing to language and transportation. During military conflicts, colonialists taken captive by aboriginal groups frequently recovered from their initial terror and were quite happily absorbed into native societies, following long-standing practice within aboriginal communities.

As an era of exploration gave way to one of permanent white settlement and aboriginal marginalization between the late-eighteenth and early-nineteenth centuries, incidents of going native took different and, generally, more limited forms. Most commonly, the desire to go native now manifested as an interest in “playing Indian.” Those who played Indian did not seek the permanent adoption of a new culture, but rather borrowed elements of native cultures to serve specific social, cultural, and sometimes political ends. For instance, during the American Revolutionary War of the 1770s, colonials borrowed aboriginal imagery (and sometimes dress) to help identify themselves with the aboriginal spirit of independence and to fashion a national identity distinct from that of their European cousins. Into the nineteenth century, members of fraternal orders adopted aboriginal dress for their initiation rituals, and native metaphors and imagery for the nationalist literature they crafted. By the early twentieth century, playing Indian was deemed especially appropriate for children. As Boy Scouts, Girl Guides, and summer campers, children were invited to emulate aboriginal lifestyles during afternoons of woodcraft, evenings of Indian council ring, and weeklong canoe trips.

By the twentieth century, only a few took their interest in playing Indian beyond the realm of leisure-time pursuits. Anthropologists, for one, occasionally lost themselves, wittingly or otherwise, in the indigenous cultures they studied. More sensationally, a few rare individuals consciously adopted new identities, attempting, frequently with success, to pass themselves off as aboriginal to white society. Naturalist and early conservationist Grey Owl and journalist and war hero Buffalo Child Long Lance were just two who reinvented themselves as Indians, gaining significant public attention in the 1930s.

As a rule, those who played Indian after the mid-nineteenth century had more limited understandings of the indigenous cultures they sought to embrace than those who went native in earlier centuries. Typically, aboriginal people were understood in simplistic and frequently inaccurate ways. Above all, to white society, native peoples symbolized innocence, connection to nature, and immersion in the simple life that white society had left behind. Those troubled by the pace and direction of modern cultural change found in this invented Indian a comforting symbol of simpler days. Even into the late twentieth cen-
Gold

Gold is a precious metal. Its several qualities have made it valuable throughout history. It is an attractive color (yellow), bright, malleable, and workable in various forms. It is also long-lasting and tough. All these properties have made it the metal of choice for decoration and art objects. Gold has also been the standard of wealth for seven thousand years, dating from the time of the ancient civilizations of Egypt and Mesopotamia. More recently, gold has become the standard of currencies.

Gold is found across a wide range of the earth’s landscape, but its accumulation in large quantities dates from the era of European explorations that began in the middle of the fifteenth century. Ventures to the New World opened new chapters in the history of gold. The first of these new stages was the Spanish conquest of the Americas with the accompanying destruction of the Aztec and Incan civilizations. Within a generation, these expeditions of plunder had produced an outpouring of gold from the New World that astonished the Old and led to endless expeditions of discovery and conquest, all in search of the legendary golden city known as El Dorado. Over the seventeenth and eighteenth centuries, the gold flowing out of the South American mines continued to dominate world production. As the nineteenth century unfolded, Russia became the leading producer. By 1847 Russia was the source of about three-fifths of the gold mined annually in the world.

The second great era of gold production was associated with major discoveries in California and Australia in the middle of the nineteenth century. In addition to the large quantities of gold harvested, these discoveries led to a new departure in the history of gold. Heretofore, gold discoveries and the gold mined from them had been a monopoly of the state. California and Australia represented a dramatic change in the sense that these mid-nineteenth century bonanzas belonged to any individual who could stake a claim. In this fashion, the gold passed directly into the hands of private citizens (or noncitizens, as was frequently the case). California’s gold production moved rapidly from $10 million in 1849 to $80 million in 1851, thereafter settling at about $40 million annually. California almost immediately produced half the world’s supply. Within the first five years, California produced as much gold as the Roman Empire had taken from the mines in northern Spain in half a century. The yields in Australia were almost as great. The Australian gold rush, like that of California, had a short life. After a dozen years, gold mining became industrialized. Still, the returns were remarkable. In the quarter century from 1850 to 1875, more gold was produced than in all the years since 1492, almost all of it in California and Australia.

The gold discoveries and the availability of these riches to anyone led to a remarkable rise in the numbers of miners. In California, the numbers rose from perhaps 5,000 in 1848 to 125,000 in 1851. This harvesting of gold on such a scale changed California from an isolated pastoral community into the most cosmopolitan place in the world. By 1852 its population had passed 250,000 people. California now became a pioneer in new patterns of rapid and intense migration associated with mining. These would include the astonishing rise of towns (and sometimes cities), the recruitment and use of labor forces, and shifts in capital and labor to remote areas all over the world. Such phenomena appeared first in California and Australia. The arrival of overseas Chinese, Irish, and other...
northern European immigrants in the gold fields created a diverse population and led to later racial strife. In both Australia and the mining camps of the American West, the Chinese were a particular target. Everywhere, whatever the racial and ethnic composition, mining camps were intensely male. Only gradually did the emerging towns come to include women and children.

At the same time, the techniques used to harvest the gold changed in decisive ways. Mining in California began with picks, pans, and shovels, as individuals and small companies washed gold from mountain streams. Within a few short years, gold mining had progressed to damming (then mining dry river beds), to hydraulic mining (using water streams to wash away hills), and to underground mining. What had begun as the work of individual miners had within a dozen years become an extension of industrial techniques, with wage laborers deep underground, complex processing machinery and plants above ground, and a stock market that enabled absentee investors to speculate.

These bonanzas of the 1850s enormously increased the world’s supply of gold. The gold reserves in the Bank of England almost doubled between 1848 and 1852; the gold inventory of the Bank of France increased seven times. Thus, the impact of the Californian and Australian gold rushes was quickly reflected in the gold reserves of Britain, France, and other powerful European nations. Great wealth also accrued to individuals and companies of various sizes. This increase led to extended debate within financial circles about the role of gold in the currencies of individual nations and the significance of gold as a worldwide standard.

The third great increase in the world’s supply was associated with gold discoveries in Alaska at the close of the nineteenth century and in South Africa at the opening of the twentieth century. The Alaskan strikes began as a reprise of the Californian dream of riches for individuals and small groups, then rapidly shifted to production by well-financed companies with the latest equipment, all within the context of a climate that severely limited the mining season. In South Africa, the gold discoveries laid the basis of some of the more remarkable mineral fortunes in the world. They also established a labor system in which thousands of black Africans labored deep in the mines for the benefit of a few white-owned South African companies. The increase in gold production in these years was notably aided by a new chemical process, the use of cyanide to recover gold from low-grade ores.

The flooding of gold into Europe at the opening of the sixteenth century and in the middle of the nineteenth century raised continuing questions about national currencies. Over the course of the nineteenth century, most major Western nations went on the gold standard; that is to say, their national currency acquired a fixed relation to gold and was supposedly freely convertible into gold at that price. England was the first to adopt the gold standard, in 1821. France, Germany, Spain, and the United States followed in the 1870s. The gold standard spread across Europe, but ended with the outbreak of war in 1914. It was re instituted in 1928. As national economies grew, nations without sufficient gold reserves (the majority of nations) supplemented their currency reserves with U.S. dollars or British pounds, thought to be the most stable of the world’s currencies. With the onset of the Great Depression, the gold standard collapsed again. Although it was restored after the war, the dominance of the U.S currency (the dollar) and dwindling gold reserves led to the gold standard’s abandonment in 1971.

GOLD, GOD, AND GLORY

Historians use a standard shorthand, “Gold, God, and Glory,” to describe the motives generating the overseas exploration, expansion, and conquests that allowed various European countries to rise to world power between 1400 and 1750. “Gold” refers to the search for material gain through acquiring and selling Asian spices, African slaves, American metals, and other resources. As merchants gained influence in late-medieval western Europe, they convinced their governments to establish a direct connection to the lucrative Asian trade, leading to the first European voyages of discovery in the 1400s. “God” refers to the militant crusading and missionary traditions of Christianity, characterized in part by rivalry with Islam and hatred of non-Christian religions. “Glory” alludes to
the competition between monarchies. Some kings sought to establish their claims to newly contacted territories so as to strengthen their position in European politics and increase their power at the expense of the landowning nobility. They also embraced the ideology of mercantilism, which held that governments and large private companies should cooperate to increase the state's wealth by increasing the reserves of precious metals. Motivated by these three aims, several western European peoples gained control or influence over widening segments of the globe during the Early Modern Era. By 1914 Europeans dominated much of the world politically and economically.

The Spanish and Portuguese were pioneers in the new era of overseas expeditions because they had a favorable geographic location facing the Atlantic and North Africa, a maritime tradition of deep sea fishing, an aggressive Christian crusading tradition, and possession of the best ships and navigation techniques in Europe by the 1400s. They were also motivated by the desire to circumnavigate the Venetian domination of Afro-Asian trade into Europe. Combining Chinese and Arab technologies with local inventions, the Portuguese, Spanish, and other Europeans built better ships to sail the rough Atlantic and learned how to mount weapons on ships, increasing their advantage at sea. The Spanish and Portuguese, using artillery, naval cannon, and muskets, could now conquer or control large territories in the Americas, Africa, and Asia, whose people lacked guns. The English were building the most maneuverable ships and the best iron cannon by the late 1500s. By the 1700s European land and sea weapons greatly outclassed those of once militarily powerful China, India, Persia, and Ottoman Turkey.

The intense competition between major European powers led to increased exploration, the building of trade networks, and a scramble for colonies—subject territories where Europeans ruled and directly controlled economic production and trade. In the later 1400s the Portuguese began direct encounters with the peoples of coastal West and Central Africa. By 1500 Portuguese explorers had opened a new era of exploration by entering the Indian Ocean, reaching East Africa, and then sailing to India. Soon, they seized several key Asian ports. Meanwhile Spanish fleets led by a Genoese mariner, Christopher Columbus, discovered that a huge landmass to the west, soon to be named America, lay between Europe and East Asia. Columbus had hoped to find the sea route to the silk- and spice-rich lands of China and Southeast Asia, and to introduce Christianity into these distant realms. Both the Portuguese and Spanish promised the pope to evangelize and colonize the “heathen” peoples they encountered.

By the later 1500s the Spanish had explored large regions of the Americas and conquered many of its peoples, including the great Inca and Aztec empires, and the Portuguese had established footholds in Brazil. Diseases brought from the Eastern Hemisphere, especially smallpox, killed off some 90 percent of the American population in the 1500s and 1600s, facilitating colonization. The only practical sea route to Asia via the Americas was finally discovered in 1520, by a Spanish expedition across the Pacific led by Ferdinand Magellan. After sponsoring their own explorations of the Americas, England, France, and Holland also colonized eastern North America and some Caribbean islands, and, like the Portuguese and Spanish, sent emigrants and Christian missionaries to what they called “the New World.”

Various European states established colonies or outposts in several African regions and carried increasing numbers of enslaved Africans to the Americas to work on plantations growing cash crops, such as sugar, cotton, and coffee, for European consumption. In the sixteenth and seventeenth centuries the Dutch colonized parts of Indonesia, including Java and the Spice islands, and the Spanish conquered and Christianized the Philippines. The English and French became active in Asia in the 1600s. American minerals supported a great expansion of the European economy and allowed Europeans to buy into the rich Asian trade, especially of goods from China. These conquests and economic activities enabled the transfer of vast resources to Europe, especially silver, gold, sugar, coffee, and spices.

Thanks to exploration and conquest resulting from the quest for “Gold, God, and Glory,” Europeans gradually brought various peoples into their economic and political sphere, laying the foundations for Western global dominance. Undergoing a profound economic, intellectual, and political transition, western Europeans left many of their medieval beliefs and institutions behind, and between 1750 and 1914 introduced even more profound changes in the world, including capitalism, industrialization, and the building of great Western empires in Asia and Africa.

Craig A. Lockard
GOLD INDUSTRY

The world gold industry is a truly unique industry. It consists of miners, refiners, traders, and hoarders. Understanding the uniqueness of the industry begins with knowing that physical gold is virtually indestructible. That is, it does not rust, corrode, or otherwise break down like other metals. The upshot of this physical quality is that every ounce of gold ever mined in the approximately seven thousand years that humans have sought gold is still around.

Identifiable aboveground gold stocks at the end of 2003 were estimated at 150,500 metric tons or 4.8 billion ounces. A majority of these stocks, 63 percent, are held in the form of fabricated products, primarily jewelry, and 35 percent is held in the form of bullion, which is gold refined to 99.99 percent (24 carat) purity. The largest part of the 52,600 tons of bullion stocks, or 29,200 tons, is held by Western central banks. The balance of bullion stocks is held by private individuals (Klapwijk et al. 2004, p. 54). A cubic foot of gold weighs approximately one-half a (short) ton (Mohide 1981); accordingly, world identifiable aboveground stocks, if brought together, would form a cube approximately 70 feet per side. It is an indication of how scarce gold is that the entire world’s supply could be stored in a modestly sized building.

Annual mine production from 1994 to 2003 ranged between 2,300 and 2,600 metric tons (74 to 84 million ounces). Because of the large aboveground stocks, annual mine supply only increases total supply by about 1.7 percent. The largest-producing countries during this period were South Africa, the United States, and Australia. The mine production of these countries declined slightly in the latter years of this period as a result of declining ore grades, higher production costs, and low gold prices. However, their production decline was compensated by rising production out of Latin America and Asia, most notably China and Indonesia.

Gold is mined at thousands of locations on all continents except Antarctica. Placer mining involves sifting and washing sands and gravels to isolate visible gold. Lode or hardrock mining involves crushing rock or soils containing gold and chemically processing the material to extract the gold. The chemical process used prior to the twentieth century was amalgamation, which involves applying mercury to the ore. The gold adheres to the mercury and can then be separated by boiling off the mercury. The amalgamation process is not only inefficient, recovering only about one-half to two-thirds of the gold, but it also does serious environmental damage if the mercury is not contained. Mercury is poisonous and does not break down in the environment. Numerous sites around the world where amalgamation is or was used remain seriously contaminated with mercury.

In the late nineteenth century, a more efficient method of processing lode ore was developed using a dilute cyanide solution to dissolve gold from crushed ore. Cyanide is also poisonous but is easier to contain and will break down in the environment over time. Recovery rates for the cyanide process range from around 70 percent for heap-leach processing (rinsing roughly crushed ore on large plastic-lined pads) to 95 percent for milling more finely ground ore in containment vessels. Depending upon the price, these higher recovery rates allow for economic recovery of gold from ores with as little as 0.01 ounces per ton of material processed—gold so fine that it can only be seen under a microscope.

Gold is mined by both “formal” and “informal” sectors. The formal sector involves sometimes large, publicly traded companies operating under the scrutiny of government environmental, financial, and other regulators. The formal sector accounts for the vast majority of world gold production. The five largest producers are Newmont Mining (United States), AngloGold (South Africa), Barrick Gold (Canada), Gold Fields Limited (South Africa), and Placer Dome (Canada). There are, however, thousands of other companies in the formal sector that explore for, mine, and trade in mining properties.

Perhaps the most controversial aspect of the gold industry is the environmental impact of gold mining and processing. Environmental regulation of the mining industry typically involves a permit process in which operators develop and get government approval of a mine and reclamation plan. These plans specify how an operator will extract and process ore, how they will store waste materials, and how they will reclaim disturbed areas. Presumably, government approval is only provided if these plans are in compliance with environmental regulations, but problematic issues include whether these regulations are adequate, whether government oversight and enforcement are adequate, and the fact that, despite the best-laid plans, accidents happen.

The informal mining sector consists of many thousands of individuals who mine gold without formal property rights or mining claims, and without the oversight of government regulators. Perhaps the most famous of the informal or “artisanal” miners are the garimpeiros of Brazil, but significant artisanal mining takes place in many other lesser-developed countries. There were an estimated eleven to thirteen million artisanal miners worldwide in 1999 (Viega and Hinton 2002). Artisanal mining involves both placer and lode mining and generally uses amalgamation for processing. The use of mercury in artisanal mining results in significant public health and environmental problems.

Artisanal miners typically sell their gold in local markets, where it is manufactured into jewelry. Operators in
the formal sector produce an intermediate product called doré whose gold content will depend upon the metallic composition of the ore. Gold frequently occurs with other metals, such as silver, arsenic, and copper, so the doré must be sent to a refinery, where it will be melted down and the metals separated. Refineries on every continent except Antarctica produce various refined products ranging from bullion bars, which are 24 carat in purity, to lower-carat alloys (18, 14, 10 carat, etc.) used in fabricating jewelry, electronics, dental fillings, and other items. These lower-carat products (as well as some 24-carat items) are sold for fabrication in the form of wire, beads, sheets, powder, and so on. By far the largest fabrication use of gold is jewelry. In 2003 jewelry fabrication accounted for 61 percent of total demand for gold, a total of 2,533 tons out of 4,142 tons sold on organized exchanges (Klapwijk et al. 2004, p. 7).

Labor market conditions in the gold industry vary greatly around the world. In South Africa and other less-developed countries, large mines can employ tens of thousands of laborers working deep underground, sometimes as much as 8,000 feet below the surface, under what most would consider harsh conditions. In contrast, in the United States most gold production comes from open-pit operations where working conditions are much better and far less dangerous. U.S. mine workers are required to undergo safety training before they are employed and periodic refresher courses thereafter, and state and federal governments conduct routine safety inspections. In general, hardrock mining is far safer than coal mining because the latter involves cutting into a combustible material, which results in explosions.

The degree of unionization of mine workforces also varies greatly around the world. South Africa’s mine workers are unionized, while in the United States most hardrock mine workers are not unionized. However, some categories of tradespeople who work at U.S. gold mines under contract, such as electricians, pipe fitters, and masons, tend to be unionized.

Labor market conditions in the informal sector are far worse than in the formal sector, primarily because of the widespread use of mercury amalgamation. Artisanal mining is generally unregulated and the use of mercury poses a significant health risk to the miners, to others, and to the environment.

Refiners also play an important role in the functioning of bullion markets by guaranteeing the purity of gold used in transactions. For historic reasons, the world bullion trade primarily involves countries in the Middle East and the Indian subcontinent as importers and European refiners as exporters through the London market. The demand side of the Asian bullion market is historically rooted in a variety of causes, some cultural, such as the giving of dowries in Muslim and Hindu cultures. But other factors, such as the historic political and financial instability of the region, play a role. In these cultures, bullion continues to play the traditional role of a store of wealth and a medium of exchange.

In Western cultures, the bullion trade arose from the historic monetary uses of gold. Most countries minted gold coin, which served as a medium of exchange. However, as fractional reserve banking gained acceptance in the nineteenth century, the use of bullion coin in trade diminished in favor of paper money issued by private banks that held bullion and bullion coin in reserve to back the paper money. At the same time, Western governments started issuing fiat money—paper legal tender backed by a fixed quantity of bullion—and maintained bullion reserves, creating the gold standard for domestic and international financial transactions. This system proved to be unstable, was modified several times during the twentieth century, and was essentially ended when the United States went off the gold standard in 1971 by refusing to redeem dollars with gold. In 2006 the U.S. central bank held approximately 8,600 tons of gold bullion at various locations but primarily at Fort Knox, Kentucky, and engaged in little if any bullion trading.

In spite of these U.S. actions, European central banks maintained various quantities of bullion stocks for traditional foreign exchange stabilization purposes and continued to be active traders in bullion markets. With the creation of the single European currency in 2000, a significant portion of these bullion stocks was transferred to the newly created European Central Bank, which uses bullion in a similar manner as the individual national banks did when they managed currencies. This changing role of gold in the monetary system has led most European banks to liquidate significant portions of their holdings, primarily shifting bullion stocks into private ownership in Asia.

Even with these significant changes in the gold market, it still works in a traditional and somewhat secretive way. The world price is set twice daily by a committee in London representing major bullion banks, including the Bank of England. In the morning the committee makes its a.m. fix, setting a price at which the banks are willing to buy or sell any quantity of gold. The process is repeated in the afternoon to determine the p.m. fix. Many contracts use the p.m. fix as the basis for transactions involving both doré and refined products. Prices in various local markets around the world will not vary significantly from the London price because gold bullion can be loaded on an airplane and shipped to or from London for a few pennies on the ounce. Gold is also traded actively in options and futures markets around the world, where a gold market is open twenty-two hours out of the twenty-four-hour day.

GOLD STANDARD

Gold has been a medium of exchange for a very long time. Although until the late nineteenth century gold had to compete with silver as the preferred standard unit of account in international financial transactions, gold has been used to measure wealth since antiquity. In the sixteenth and seventeenth centuries, following the discovery of rich gold mines in the Americas, the prevailing economic theory, mercantilism, recommended the pursuit of restrictive trade policies designed to discourage the importation of foreign goods and to encourage the exportation of domestic goods so as to increase the stock of precious metals, and of gold in particular, in the treasuries of the most important European kingdoms. But the gold standard refers to a more recent and specific phase in monetary history—a phase that is now past, and probably irrevocably so. Most contemporary economics textbooks pay only scant attention to it (Kimball 2005). A few economists, however, still advocate a return to the practices that defined the gold standard for reasons that are discussed further below.

Under the gold standard, as it began to take shape in the 1870s, currencies were backed by gold exclusively. Within a country, paper money could be redeemed for a guaranteed amount of gold and, internationally, fixed exchange rates determined the quantities of gold that central banks could use to clear international balance of payment accounts. In practice, however, this strict principle allowed for a limited degree of flexibility allowing the central banks of the countries that adhered to the gold standard regime to engage in a variety of manipulations (e.g., convertibility was severely limited in many of the less powerful countries). Great Britain was almost continually on a gold standard from the 1750s until 1913, with the exception of about two decades (1798 to 1821) when the Napoleonic wars and their aftermath forced the Bank of England to issue nonconvertible paper currency. Most of the other powers, however, including the United States, based their currencies on both gold and silver until the 1870s. (In fact, the word for silver in French also means money.) But by the 1870s because the price of silver had become too unstable, most European powers and the United States chose to hold only gold in their bank reserves, and to officially establish the convertibility of their currencies in gold only. By the 1890s a process of gold standardization had occurred: Most countries were by then part of an international financial regime based on a fixed exchange rate for gold.

The transition to the gold standard was not entirely smooth. There were political interests that opposed it. In the United States, for example, farmers in the Midwest continued to support a return to bimetallism for about two decades after the United States (unofficially) adopted the gold standard in 1879, in part because they felt that the rules of the gold standard made it more difficult for them to obtain credit and made them more dependent on what they perceived as the whims of the “eastern banks,” impersonated as the wicked Witch of the East in L. Frank Baum’s fairy tale The Wizard of Oz. In fact, the United States did not legally switch to the gold standard until 1900 (Littlefield 1964).

BEFORE WORLD WAR I

The pre–World War I gold standard worked very efficiently as a means to maintain price stability. Gold, and to a lesser extent British pounds, flowed between countries to compensate for trade surpluses and deficits. In theory, the system functioned automatically: If the real exchange rate for a given currency was above the nominal exchange rate in gold, exports suffered and imports increased, creating a balance of payments deficit; external creditors asked to be paid in gold and the resulting outflow of gold had the effect of lowering domestic prices, thereby stimulating exports and discouraging imports and eventually bringing down the real exchange rate nearer to, or even below, the nominal rate, and the pendulum swung in the other direction. The monetary authorities were expected to take appropriate measures to facilitate this process: raising the bank rate, which, in turn, led to rising interest rates, in order to decrease investments and reinforce the deflationary effect of an outflow of gold, while at the same time ensuring that the outflow of gold would not continue indefinitely, or lowering it to reinforce the inflationary effects of an inflow of gold, but also thereby preparing the ground for a reduction in that inflow. That these measures often had a deflationary effect was of little concern at a time when governments were not held responsible for unemployment. The effectiveness of the system was rein-
forced by the fact that investors, often anticipating the measures that monetary authorities were about to adopt, moved their funds from country to country, thereby bringing about the equilibrium that these measures would have reestablished and diminishing at the same time the need for such measures.

Already in the years immediately preceding World War I there were signs of tension in the system. The outbreak of the war led to its collapse. The interwar years were much more troubled as far as the international monetary system is concerned. Although most nations that had suspended convertibility into gold re instituted it in the 1920s, it never functioned as well as it had before the war and by 1937 it had been abandoned by all countries. (Germany had done so in 1931, Britain in 1933, and the United States in 1933; France and Japan held on until 1936.) There is no complete agreement on the question of whether the demise of the gold standard was brought about by the Great Depression or whether the gold standard was itself a major cause of the severity of the depression. The latter thesis points to the fact that the United States and France, two countries with trade surpluses, together held more than half of the gold while also pursuing deflationary policies, which led to a contraction of the money supplies in much of the rest of the world that made it impossible to initiate expansionary programs in timely fashion to deal with the onset of the depression (Bordo 1993; Eichengreen 1992). But what is certain is that at the end of World War II, the gold standard was widely regarded as having been a failure.

THE BREITON WOODS AGREEMENT
The participants in the 1944 conference held in Bretton Woods, New Hampshire, were seeking to establish an international system that would retain the stability and predictability of the pre-World War I gold standard but would not cause the rigidities that many then suspected had significantly contributed to the worsening of the worldwide 1930s depression. The agreement they adopted resulted in a system that was still, at least indirectly, based on gold, although by this time only the U.S. dollar was directly convertible into gold, and only among central banks. However, all signatories to the Bretton Woods Agreement were committed to maintaining something approximating fixed rates of exchange in relation to the dollar, but with enough flexibility to allow them to manage their economies so as to produce full employment. Hence dollars rather than gold became the main components of the reserves of most central banks. The heyday of that system from the mid-1950s to the mid-1960s coincided with—and to an extent that is difficult to measure, helped to bring about—a period of exceptional economic growth (especially in western Europe and Japan) and expanding international trade. But it also placed severe constraints on the United States. By 1971 the United States had definitely ceased to guarantee the convertibility of the dollar. Since that date gold has been demonetized, even though the central banks of many countries continue to hold more or less significant stocks of gold. Floating rates are now the rule, with the exception of some countries that have more or less permanently pegged their currencies to a stronger one or others, such as the euro zone, that have established a monetary union.

A return to something like the gold standard has been advocated by some economists, notably those associated with the school of thought known as Austrian economics, so named because it can trace its roots to the writings of prominent Austrian economists such as Carl Menger. Adherents of Austrian economics have very little confidence in the ability of governments and central banks to effectively guide the course of economic events. It is, therefore, the self-regulating nature of the old gold standard that leads them to advocate revisiting this concept. They usually recommend the creation of a system in which the central banks would be forced to “play by the rules,” if necessary by privatizing these banks. Although this would certainly offer strong guarantees against inflation, the need for such a system appears less compelling in the early twenty-first century than it did in the 1970s and 1980s, when inflation was much more of a threat than it has been since then. There is very little political support in the world for such a reform.

GOLDEN RULE IN GROWTH MODELS

The Nobel laureate Robert M. Solow (b. 1924) famously argued that a steady state growth will involve a higher savings and a higher capital-to-labor ratio to achieve a higher per capita income. Higher per capita income, however, does not automatically imply higher per capita consumption. Therefore this is a typical case of optimization in which we have to find the level of capital-to-labor ratio that provides at the same time the maximum possible per capita consumption. This problem was posed initially by Edmond Phelps (1961), and the solution provided was called the golden rule of accumulation (growth). According to this rule, an economy reaches the optimum growth rate at the point where each generation saves and invests at the level that it wishes the previous generation would have invested. That is, each generation saves (on behalf of future generations, as it were) that fraction of income that it would have liked past generations to have saved, subject to the constraint that all generations past and present are to save the same fraction of income. This condition requires that the rate of profit (interest) equals the rate of growth of an economy.

Let us define the per capita consumption \( c \) as the difference between the per capita income \( f(k) \) and the per capita savings/investment \( sf(k) \), that is: \( c = f(k) - sf(k) \). Equilibrium is attained at the point where the per capita saving (investment) is equal to the amount needed to keep the increasing labor force \( n \) with the same capital equipment (growth rate of capital labor ratio equals zero). Formally, \( sf(k) = nk \). If we now revise the previous equation accordingly, we have \( c = f(k) - nk \). Because we are not interested in any level of consumption, but rather the maximum possible, we get the first derivative of the above equation and we set it equal to zero: \( dc/dk = f'(k) - n = 0 \) and \( f'(k) = n \). Thus the marginal product of capital (read rate of profit) equals the growth rate of the economy, because at the steady state growth rate, the growth rate of output equals the growth rate of labor force.

It is clear that public policy and private propensities can be designed to achieve this golden rule. That is, for example, even though a relatively low capital-poor economy will pursue optimum growth by steadily increasing its capital-to-labor ratio, it may accomplish this by saving relatively more in the future than in the present. However, major concerns about the existence of the golden rule of growth have been raised that refer mainly to the conditions for its existence. Some economists suggest that the rule exists only in neoclassical models in which capital and labor are continuously substitutable, there is no technical progress, unlimited influence on subsequent generations’ choices is present, proper population policies exist, and so on. Phelps showed that the golden rule “always exists in the neoclassical and Harrod-Domar models if the labor force increases at a constant rate, the depreciation rate is constant, technical progress, if any, is purely labor-augmenting, labor augmentation occurs at a constant rate, and positive labor is required for positive output” (Phelps 1965, p. 812). Otherwise, the growth paths are dynamically inefficient and the golden growth rate of accumulation is unattainable.

GONE WITH THE WIND

Margaret Mitchell, a descendant of the southern aristocracy of Atlanta, Georgia, and a former writer for the Atlanta Journal, was author of the 1,037-page Pulitzer Prize–winning novel Gone with the Wind. The novel represented a culmination of her family’s southern history, Atlanta’s local history, and the South’s reconstruction in the aftermath of the Civil War.

SUMMARY

Depicted through the gaze of the novel’s protagonist, Gone with the Wind features Scarlett O’Hara, one of the most popular southern belles in Clayton County, Georgia. Scarlett is a woman with a determined spirit and uncompromising sensibility, willing to do whatever is necessary to survive and to maintain her home, the Tara plantation. In the turbulence of the Civil War, Scarlett’s love life is entangled when Melanie Hamilton marries the object of Scarlett’s desire, Ashley Wilkes. Disillusioned, Scarlett marries Melanie’s brother, Charles, but their marriage is short-lived due to his untimely death as a Confederate soldier. As the war continues, Melanie and Scarlett find themselves caring for wounded soldiers. Attacked by Yankee forces, both women are compelled to flee, Melanie...
with her newborn baby and Scarlett with her surrogate family—her black servant, Prissy—an escape assisted by Rhett Butler, a blockade runner and outcast.

At Tara, Scarlett discovers that her mother died, and the plantation, with only a few faithful slaves, was nearly destroyed. In dire straits for money, Scarlett returns to Atlanta to secure funds from Rhett. Again, in an effort to save the plantation, she marries, this time her sister's fiancé. Exhibiting independence and entrepreneurship, Scarlett purchases and operates a lumber mill; this results in her becoming the victim of an attack and in her husband’s death.

Although still maintaining her affection for Ashley, Scarlett reunites with Rhett and is provided with an enormous estate and luxuries. She has Rhett’s child, a daughter (her third child, as she had two children in prior marriages), but the daughter is accidentally killed, devastating both Rhett and Scarlett. As the novel ends, Melanie, facing death, entrusts Scarlett with the care of Ashley, but now Scarlett recognizes that her real love is for Rhett. By this time, however, Rhett has lost his affection and respect for Scarlett, demonstrated by his dramatic exit at the novel’s end.

In addition to winning the Pulitzer Prize and becoming a Book of the Month selection, Gone with the Wind sold over one million copies in its first year of publication. Its popularity as a literary work has been debated by a number of critics who attribute Mitchell’s success to her ability to infuse characters with captivating attributes; or to her ability to reconstruct southern history in an emotional and meaningful way from the perspective of a victim who is also a survivor; or to her ability to convey hope and optimism in the face of despair and defeat; or to its interdisciplinary appeal as a literary work to those interested in the military, in geography, anthropology, psychology, sociology, and in other fields.

Mitchell’s novel provided a response to the mythical view of the Lost Cause fueled by the defeat of the South in the aftermath of the Civil War and represented by the loss of wealth and power, as Atlanta was reduced to ruins. Despite the wealth formerly achieved from the South’s plantation economy and idealized by its glamorized past, Mitchell’s work responded to the Lost Cause myth through the assertiveness and aggressiveness of her protagonist, Scarlett—a character who symbolized that the South could emerge from its past degradation and despair.

In 1936, producer David O. Selznick purchased the screen rights to the novel for some $50,000—at that time one of the largest sums ever paid for a screenplay. The film’s production was complicated by changes in the director and scriptwriters, searches for appropriate actors, and other problems. Rhett Butler, played by Clark Gable, was reluctant to accept the role, although he was the public’s popular choice. Scarlett O’Hara, played by British actress Vivien Leigh, won the role despite consideration of a number of widely known American actresses such as Katharine Hepburn and Bette Davis. The film cost some $4.25 million and ran well over 3 hours and 40 minutes. Appearing in the novel but not in the film were Scarlett’s first two children, Rhett’s blockade activities and his relationship with Belle Watling, and the Ku Klux Klan.

COMPARISON OF GONE WITH THE WIND AND BIRTH OF A NATION
Gone with the Wind was widely compared with the film Birth of a Nation (1915), based on Thomas Dixon’s novel The Clansman and produced by D. W. Griffith. Both films were Civil War epics, both were massive productions, both attempted to capitalize on historical facts, and both were regarded as controversial because of their racialized representations. These two films were also similar in sharing a common respect for the dramatization of American history by foregrounding the importance of romance and family. Birth of a Nation was nearly an attempt to embrace and resuscitate the past, while Gone with the Wind acknowledged the past from which it was fleeing and utilized this past as a means to reconstruct a new future and a new identity.

Both films endured censorship difficulties, with Birth of a Nation facing numerous censor boards prior to its exhibition because of its racial politics. Gone with the Wind challenged the Production Code’s profanity restrictions with Butler’s famous line, “Frankly, my dear, I don’t give a damn.” Birth of a Nation spawned riots in some northern cities and invited protests. Gone with the Wind, in comparison, elicited protests even prior to its completion and raised the ire of black newspapers.

FILM’S RECEPTION
Carlton Moss, an African American dramatist, submitted a letter to Selznick in 1940 that appeared in the Daily Worker. The letter outlined the racial insults committed by Gone with the Wind and suggested that it fabricated the myths that blacks were not concerned with freedom and that they lacked the innate ability to govern themselves. These views were echoed by members of the black press. The New York Amsterdam News described Gone with the Wind as the “pus oozing from beneath the scab of a badly healed wound.” The Chicago Defender charged that the film glorified slavery and depicted the black male as a “grotesque and ravishing beast.” The Crisis expressed its objections to the film’s racial epithets. These offenses were further compounded when black actress Hattie McDaniel was not invited to attend Gone with the Wind’s Atlanta premiere in December 1939. In spite of such derision, McDaniel received an Academy Award as best supporting...
actress for her role as “Mammy,” becoming the first African American to receive this award.

The mainstream press was much more enamored with the film. The New York Times claimed that while the picture may not have been the greatest motion picture ever made, it was “the greatest motion mural … seen and the most ambitious film-making venture in Hollywood’s history.” Other critics noted that the film was extremely well cast and acted with “costuming … above reproach; the interior sets are first rate; [and] much of the Technicolor photography is beautiful.” The film’s overwhelming reception, coupled with its movie attendance records, was further testament to its appeal and popularity. When Gone with the Wind premiered, some 55 million people reported that they intended to see it. Over one million people traveled to Atlanta for the film’s premier, which was accompanied by parades and celebrations. Added to these accolades, the film won ten Academy Awards, including an award for best picture.

**FILM IMPACT AND SUBSEQUENT WORKS**

Gone with the Wind was a powerful force in garnering sympathy for the South in the postbellum period. One critic suggested that even northerners stood to be influenced by this southern mythology to the extent that though the North and South were once divided, northerners were now willing to join southern forces and “whistle Dixie.” The film’s impact continues to evolve with subsequent releases. The impact of both the novel and the film is further apparent when the Mitchell estate commissioned Alexandra Ripley to write a sequel to Gone with the Wind, titled Scarlett and published in 1991. This novel was also transformed into a 1994 television miniseries, titled Dixie. The film’s impact continues to evolve with subsequent releases. The impact of both the novel and the film is further apparent when the Mitchell estate commissioned Alexandra Ripley to write a sequel to Gone with the Wind, titled Scarlett and published in 1991. This novel was also transformed into a 1994 television miniseries, but it met with much less success. Variety stated that “viewers’ best hope, however, is to try to forget that classic book and film, and approach Scarlett for what it is: an eight-hour bodice-ripper.”

Interest in the novel was reigned when Alice Randall published The Wind Done Gone in 2000, described as a parody of Gone with the Wind. Randall’s work challenges the views propagated by Gone with the Wind by creating characters antithetical to those in the previous work. The Wind Done Gone provoked controversy, with many critics claiming that Randall infringed on the copyright of the 1936 novel. In a legal dispute to prevent the publication of Randall’s work, the court found it to be distinctly different from Gone with the Wind in that it explored the intersection of race and sex and defied the myth of black savagery and primitivism.

Both the novel and the film continue to surface in contemporary discussions and debates, with the film becoming an integral part of the American literary canon. Gone with the Wind has solidified its place in American history and cinema—capturing and marking historical moments that deserve to be returned to again and again.

GOODS, NONTRADED

While international trade involves the international shipment of an incredibly diverse range of goods and services—from cars, furniture, and insurance to umbrella knobs, pedestal actuators, holiday ornaments, and tax preparation services—not all products and services are internationally traded. Those products or services that are not exported are called nontraded goods.

There are two reasons that goods are not traded. The first reason is obvious: it is impossible to ship certain products from one country to another. A haircut is the prototypical example of a nontraded good. This service cannot be ordered for international shipment; the customer must travel to another country to visit a foreign barber, or the barber must travel to cut the customer's hair in the customer's country.

The second category of nontraded goods involves products that could be transported internationally but remain nontraded because the economic benefits of international trade are offset by the costs of trade. For example, while cement can be exported, it is generally unprofitable to do so because of the high transportation costs of moving such a heavy and bulky product. Thus, some products will be traded between countries that are close to each other and have low trade costs, while the same products will not be traded between countries that have high trade costs due to their distance from each other. In addition to transportation costs, other barriers to trade—such as tariffs or quotas, the inability to ship a product in a timely manner, or the inability to ship a product before it spoils, also cause a number of products to remain nontraded.

Nontraded goods may become traded goods when the original impediments to international trade decline sufficiently to make international trade profitable. In addition, advances in technology reduce the range of products that are nontraded. For example, since optimal patient care requires physicians to rapidly diagnose an illness or assess the severity of an injury, the reading of X-rays was originally performed by local radiologists in the patient's and doctor's country of residence. As a result, the need for immediate assessment and evaluation of X-ray results caused diagnostic services to be internationally nontraded. However, radiological services became tradable when improvements in communications technologies made it possible for X-ray technicians to quickly send electronic images of X-ray results to radiologists in other countries for immediate analysis.

The prevalence of nontraded goods has implications for national economies. First, as formerly nontraded goods become tradable, a wider range of a country's production is organized according to international comparative advantage. A trading country reaps economic benefits from the efficiency improvements that are made possible by this change. In addition, fundamental differences in the nature of traded and nontraded goods have implications for cross-country differences in economic outcomes. According to the hypothesis known as the Balassa-Samuelson effect, the higher rates of productivity growth in traded goods can help explain the cross-country observation that prices are higher in high-income countries than they are in low-income countries.

GOODWILL

Goodwill is the value placed on the expectation that the clients or customers of an established company will continue to patronize it out of habit or confidence in the conduct of its business. In practice it is simply the amount by which the price of a going concern exceeds the sum of fair values of all of its other net assets. In other words, it is the amount of money that may be paid to the owners of a business over and above the costs of merely buying the assets that the company uses.

The origin of the term lies in developments in accounting that accompanied the rise of the capital market in the second half of the nineteenth century. The easing of the establishment of joint stock companies during this period facilitated the purchase of many retail businesses, whose previous owners were paid for referring their previous customers to the business under new management or ownership. Goodwill came to be used to pay the existing owners of a company's equity a price for their stock inflated above the value of any actual underlying assets by the more active capital markets of the late nineteenth century. The American political economist Thorstein Veblen regarded goodwill as reflecting competitive advantages, which a company may have and which may not be incorporated in the cost of assets. In the course of mergers and acquisitions, the value of a company's stock comes to reflect its increasingly monopolistic market position. However, John Hobson and Alfred Marshall expressed a more common view in the first decades of the twentieth century that goodwill was used to exaggerate a company's business prospects leading to the overcapitalization of that company. In this way financiers
and company promoters profited at the expense of the investing public. Despite the relevance of these views, there was little discussion of them amid the inflated capital markets of the late twentieth century and early twenty-first century.

Goodwill purchased in the course of buying a company has wider implications because the cost of it is treated as a business expense. In the United States and Canada this expense is amortized against company earnings over a period of up to forty years. Because, after a company has been purchased, these amortization payments are purely bookkeeping transactions, it has been argued that the recording of these payments in the income and expenditure statement of a company makes that statement less clearly a reflection of actual business income and expenditure. In the United Kingdom an accounting standard in force since 1984 recommends that goodwill should “normally” be written off immediately after acquisition against the owners’ equity or reserves. However, such immediate write-off can lead to extreme shifts in the “leverage” or gearing of a company (the ratio of its debt to equity). It is not unknown for such a write-off to result in negative owners’ equity. Even before that arises, the sudden fall in the value of owners’ equity may cause difficulty where a company has loan agreements that stipulate a maximum permissible leverage ratio. Such shifts in the value of owners’ equity also affect the vulnerability of a company to takeover or even to reporting, as the London Stock Exchange obliges its companies to do, where the payment for a company represents 15 percent or more of the acquiring company’s equity.

Because business expenses reduce the tax liability of companies, the accounting treatment of goodwill—that is, whether and how it is amortized—may have significant tax implications for a company. Among service companies with limited scope for capital investments that may be set against tax over a period of years, goodwill may be an important factor in the tax planning of a company.

The significance of goodwill in corporate finance has been inflated by the proliferation of mergers and takeovers in active capital markets. The emergence of such markets in Europe and other parts of the world extends the geographical area where goodwill has fiscal and accounting importance.

GORBACHEV, MIKHAIL

1931–

Mikhail Gorbachev, leader of the Soviet Union from 1985 until that country’s demise in 1991, has gone down in history for peacefully dismantling the seventy-year-old repressive Communist system and for initiating the cold war’s nonviolent end after four decades of international tension. For this, he received the Nobel Peace Prize in 1990 and is regarded by many, particularly outside Russia, as one of the twentieth century’s greatest leaders. Inside Russia, Gorbachev is more often blamed for the collapse of the Soviet Union, a breakup most Russians regret. Whether Gorbachev should be held directly responsible for that collapse is contested by many scholars who cite complex reasons for that country’s disintegration.

Born into a peasant family, Gorbachev grew up in the important agricultural region of Stavropol, in southern Russia. Highly intelligent and winning awards for both academic achievement and agricultural work, Gorbachev was accepted to the prestigious law faculty of Moscow State University in 1950. There, Gorbachev met educated, urban students from the U.S.S.R. and Eastern Europe, one of whom, the Czech intellectual Zdeněk Mlynář (1930–1997)—later a prominent 1968 Prague Spring reformer—became Gorbachev’s lifelong friend.

Returning to Stavropol in 1955, Gorbachev advanced to the top of the regional party hierarchy, and by 1978, he reached Moscow as the secretary of the central committee of the Communist Party of the Soviet Union (CPSU) in charge of agriculture. By 1980 this young, energetic agricultural expert was elected as full member of the fourteen-strong Soviet Politburo (the highest Soviet decision-making body, stocked with octogenarians). Once the CPSU general secretary Leonid Brezhnev died in November 1982, Yuri Andropov emerged victorious from the leadership struggle, only to die fifteen months later and be replaced by the ailing Konstantin Chernenko, who survived for only thirteen months. Gorbachev became general secretary, and thus Soviet leader, in March 1985.
With skillful use of his new powers, Gorbachev pushed aside the old guard and reassigned top posts to like-minded anti-Stalinists such as Eduard Shevardnadze (b. 1928) and radical reformers, notably Aleksandr Yakovlev (1923–2005). He then embarked on diplomatic campaigns abroad that, over five years, grew into a foreign policy revolution featuring massive, asymmetrical cuts in Soviet weapons arsenals, acceptance of the peaceful liberation of Eastern Europe, and finally, a radical push to join Europe as a democracy.

At home, Gorbachev managed—despite incessant opposition—to introduce increasingly important political reforms, dubbed perestroika (political and economic restructuring) and glasnost (openness in media and society). Though always predisposed toward reform, Gorbachev did not stress democratization until 1987, when his powers had grown strong enough and his own views consolidated. In 1988 he established competitive elections and a genuine legislative body. He worked to implement checks and balances, a law-governed state, political and religious freedoms, and genuine federalism. Radical economic reform proved far harder, because liberalizing prices risked social upheaval. The economy stagnated as the command economy unraveled, while market institutions remained unborn. The combination of political freedoms, high expectations, and economic decline exacerbated tensions between the fifteen republics and the Soviet state. Striving to keep the U.S.S.R. together, Gorbachev embarked on a new federal framework; but politics at home undercut him. An attempted coup in August 1991 left him critically weakened. In December Boris Yeltsin (1931–2007), president of the Russian Republic, dealt the final blow to Gorbachev—and to the Soviet state. Striving to keep the U.S.S.R. together, Gorbachev embarked on a new federal framework; but politics at home undercut him. An attempted coup in August 1991 left him critically weakened. In December Boris Yeltsin (1931–2007), president of the Russian Republic, dealt the final blow to Gorbachev—and to the Soviet Union. Gorbachev resigned, leaving a great legacy. He brought freedom to Russia and played the most decisive part in ending the cold war.

**GOSNELL, HAROLD**

1896–1997

Harold F. Gosnell played a major role in the development of the scientific approach to political research. He was among the first political scientists to utilize randomized field experiments, correlation, regression, and factor analysis, which he skillfully blended with archival research, participant observation, elite interviewing, and ethnography to produce seminal studies of elections, voting behavior, party politics, political machines, and African American politics.

Harold Gosnell grew up in Rochester, New York, and received a bachelor’s degree from the University of Rochester in 1918. He matriculated as a graduate student at the University of Chicago, where, under the tutelage of Charles Merriam, he received a PhD in 1922. Gosnell immediately joined the political science faculty at the University of Chicago, where he was part of the nucleus of the Chicago School of Political Science, which endeavored to construct a science of politics on the model of the natural sciences.

Gosnell was deeply concerned with the functioning of elections and the factors that led citizens to participate in them or not. His *Non-Voting: Causes and Methods of Control* (1924), authored with Merriam, examined a random sample of 6,000 nonvoters in the Chicago mayoral election of 1923. It identified the principal causes of nonvoting as non-registration, disbelief in women’s voting, disgust or indifference, and physical impairments or difficulties. Merriam and Gosnell argued that efficient party organization and simplification of registration laws would enhance citizen participation in elections. In *Getting Out the Vote* (1927) Gosnell conducted randomized field experiments in the Chicago elections of 1924 and 1925 to determine whether nonpartisan notices could stimulate citizen registration and voting. He found that a nonpartisan appeals could boost registration by about 9 percent but mattered less where party organizations were strong and education levels high; they had a greater marginal effect on women, African Americans, and the less educated.

A fascination with party organizations, especially political machines, permeated almost all of Gosnell’s work, starting with the first of his twelve books, *Boss Platt and His New York Machine* (1924), which traced the rise and fall of machine politics in New York. In *Negro Politicians* (1935) he documented changes in Chicago politics brought about by the northward migration of African
Americans, their loyalty to and role in the Republican Party, and the first signs of shifting loyalties to the Democrats after the initiation of the New Deal. He detailed the centrality of black churches and the black press (especially the Chicago Defender) in mobilizing opinion and sustaining organization in the community. Gosnell generalized his arguments on party organization in Machine Politics: Chicago Model (1937). He demonstrated the success of ward bosses and precinct captains in insulating the parties from broader trends in national politics brought about by the Great Depression. Gosnell saw ballot simplification, proportional representation, civil service laws, and other reforms as ways to wean democracy from the imperatives of patronage and graft.

Gosnell left Chicago in 1941 for Washington, D.C., where he held positions in several federal agencies and then served as professor of political science at Howard University from 1962 to 1970. The American Political Science Association recognizes his achievements by awarding each year the Harold F. Gosnell Prize of Excellence for the best work of political methodology presented at a political science conference.

GOULD, STEPHEN JAY
1941–2002
Stephen Jay Gould was a paleontologist, evolutionary biologist, essayist, and public intellectual. He lived a rich life achieving heights of academic success as a professor at Harvard University as well as attaining public recognition as an erudite, literate scientific essayist. Gould’s importance stems from his distinctive and important contributions as an evolutionary biologist and paleontologist, as well as his participation in public debates bringing his humanist and scientific commitments to bear on important social and scientific issues.

As a biologist Gould is best known for the theory of “punctuated equilibria” which he formulated jointly with the American paleontologist Niles Eldredge. The fossil record is an imprint of the past providing researchers with extensive evidence not only for the fact of evolution but a detailed map of the branching pathways connecting the diversity of life. The evolutionary paths emanating from different life forms can be traced through the chronological ordering of this fossil record. In standard Darwinian explanation the pace of evolutionary change is assumed to be slow. Accordingly, small incremental changes are accumulated to amount eventually to the grand differences that scientists associate with distinct species. The fossil record, however, does not show continuous change between life forms; rather there seem to be gaps. These discontinuities in the record could reflect scientists’ incomplete knowledge or simply gaps in the fossil record itself. Gould and Eldredge attempted to explain the “gaps” in the fossil record by questioning the assumptions made about the pace of evolutionary change. They argued that for long periods species enjoy stability, giving way to rapid and drastic change over short periods of time. Thus, the so-called gaps in the fossil record actually reflect a fact about the pace of evolutionary change rather than representing missing evidence.

Gould viewed evolutionary biology as a historical science. To him evolution was not a deterministic unfolding of events but a process highly contingent on the vicissitudes of circumstance. His views brought him into conflict with some of his peers who tried to veer evolutionary biology toward a more mechanical paradigm in which the evolutionary process was reduced to natural selection operating at the genetic level. Perhaps his most visible sparring partner in this debate was Richard Dawkins, who had presented arguably the strongest version of the mechanical paradigm. Dawkins envisioned organisms as “lumbering robots” carrying out instructions encoded in the organism’s DNA. Dawkins departed from orthodox Darwinism in placing the gene as opposed to the organ-
First, he argued that natural selection, while an important and perhaps even dominant motor of evolution, was not the only driving force. He derided the pans- 

lectionism of his opponents as a “panglossian paradigm” in which every feature of the organism was furnished with an adaptationist “Just So” story—a reference to Rudyard Kipling’s humorous children’s stories, particularly the ones about the origin of features of animals. Gould considered a multiplicity of mechanisms as important in evolution. These mechanisms included random reproductive success of some features due to the dynamics of finite populations, as well as structurally inevitable correlates of selected features where these correlates provide no reproductive advantage.

Second, Gould opposed reduction of evolution to the level of genes. He accepted as a fact that genes are responsible for the heritability of traits, but argued that selection occurs at the level of the organism per the Darwinian paradigm. Evolution to Gould could not be understood unless one allowed for different hierarchical levels of study; this hierarchy included the genetic level, the organism, and the species—each one important for a different set of evolutionary questions.

Third, Gould argued that the reduction of the organism to its genotype led ineluctably to a whole set of mistaken ideas which he collectively termed biological determinism. Biological determinism, as expressed in the ideas of sociobiology and evolutionary psychology, is the belief that complex behavior of organisms can be understood as following from the organism’s genetic make up, and are thus permanent features of the organism. As an example, a determinist might argue that a person’s genes determine her or his level of intelligence.

Gould went on to understand the questions that biological determinists tried to answer as historically conditioned. He saw in the determinist program a program that justified the stratification of our present-day society along gender, racial, and economic lines by providing these social realities a biological justification.

Gould’s scientific interests intersected significantly with his social commitments. He participated in public debates arguing against creationism and the genetic basis for behavioral differences between racial, gender, and class groupings. He wrote prolifically for the lay public on science, history, and society and achieved a considerable amount of fame and influence as a writer of popular science.

GOVERNMENT

Government is as old as human beings themselves. All human societies are governed by rulers, no matter what their titles and characteristics may be. On the theoretical level, government is intrinsic to human societies. Nevertheless, at a more tangible level, nothing about government is static. Structures and functions of governing are constantly in change.

The word government has a Greek origin, kyvernites, which means “governor,” or “rudder.” Government is a body or organization that has the power to make and enforce laws and regulations for a certain territory. Government refers to the act of governing, meaning exercising authority over a community or a country. It is a system by which a political unit is governed. The two central features of government are the ability to make collective, binding decisions and the capacity to enforce them. Thus, the core functions of modern government are to make law (legislation), to implement law (execution), and to interpret law (adjudication). On the national level, the basic duty of any government is to ensure a country’s survival. Survival involves two basic tasks: defending independence against external threats, and maintaining internal security and preventing civil war or secession. In parliamentary systems, the political executive alone is referred to as “the government.”

Each efficient government should have an authority, or a “legitimate power.” Power is the ability to influence the behavior of others, whereas authority is the right to exercise that power and to get the people’s obedience by using various means, including direct physical coercion, threats, exile, banishment, and so on. Such an authority should be legitimate, that is, as Max Weber noted, the use of force by a government should be recognized as legitimate and justified by both the powerful and the powerless. Legitimacy is considered a basic condition for
governing, and without a minimal amount of legitimacy, a government will deadlock or collapse.

Government differs from other social or private organizations in many ways, as noted by Austin Ranney (1996). It has legitimate monopoly of vast force (the army, the police, etc.), and can use coercion to enforce its rules and to punish rule breakers. Furthermore, government has inclusive and authoritative powers; that is, whereas rules made by nongovernmental organizations apply only to the members of those organizations and often conflict with those set by other organizations, governmental rules apply to all members of the country and usually are considered to be binding upon all members of a society. In any conflict between the decisions of government and the decisions of nongovernmental organizations, government decisions should prevail. Additionally, while membership in most organizations other than government is voluntary, citizenship is largely involuntary; most people become subject to governmental rules and decisions without any intentional choice.

FORMS OF GOVERNMENT

There are several ways to classify governments. One traditional classification is based on who holds political power: one man or woman (autocratic government), a few (oligarchic government), or a majority (democratic government).

An autocratic government is a government in which one individual holds all power, as is the case in absolute monarchies and dictatorships. One feature of most hereditary monarchies is that the monarch usually rules as head of state for life. In absolute monarchies, monarchs hold substantial power over every aspect of the country. Contemporary examples of such a form of government include Brunei, Bhutan, and Saudi Arabia. In other hereditary monarchies, real authority is held by military rulers, as was the case in Japan during the eighteenth and nineteenth centuries. Under the fascists Benito Mussolini (1883–1945) in Italy and Francisco Franco (1892–1975) in Spain, the two countries were officially monarchies. Some current monarchies are established by tradition, thus the monarch has little real authority. Examples of such a form of government include democratic constitutional monarchies in the United Kingdom, Canada, New Zealand, and Spain.

Dictatorships are usually regarded as synonymous with other forms of autocratic governments, such as totalitarianism and authoritarianism, though each of these forms has a different meaning. Dictatorship refers to absolute, repressive rule by one leader who is unrestricted by any law or constitution. Many dictators tend to suppress any opinion that disagrees with their own, and often use military and security forces, propaganda, and arbitrary detention to enforce their will. Such dictatorships survive because of the fear of the dictator. Some dictators create single-party regimes, without democratic elections or with rigged ones, in an attempt to acquire popular legitimacy.

Totalitarian government is a term employed by political scientists to describe modern regimes in which a regime regulates nearly all aspects of public and private behavior. Totalitarian rulers mobilize entire populations in support of the state and a political ideology. Such rulers do not tolerate political activities by individuals or groups such as labor unions and political parties. They maintain themselves in power by means of widespread use of terror tactics, secret police, a one-party system, propaganda, and restriction of freedoms and free discussion. Examples of such regimes include the Soviet Union and the Nazi regime of the 1930s and 1940s.

Authoritarianism is a form of government in which rulers are not appointed via free and fair elections. Authoritarian leaders tend to enforce strong and oppressive acts against those in their domain of influence. Examples of such regimes include the People’s Republic of China and Cuba.

In contrast, an oligarchic government is a government where political power is held by a small group of individuals such as aristocrats (the upper class) or plutocrats (the wealthy). Another example of an oligarchic rule, one based on race, was in South Africa under the apartheid system, where the white minority held power. Some theorists such as Gaetano Mosca, Vilfredo Pareto, and Robert Michels argue that in a capitalist society, political and economic power is held by a few members of the capitalist class that seek to maintain the capitalist system at the expense of other classes. In his book Political Parties (1968), Michels mentions the “iron law of oligarchy,” arguing that all forms of organizations, including the political system, will eventually develop into an oligarchy.

A democratic government is one in which the majority of the people hold political power. Democracy could be direct (all citizens exercise power, as was the case with Athenian democracy) or indirect (where power is exercised by elected representatives, as is the case with contemporary representative democracies in the West). The core characteristic of a democratic government, in the contemporary usage, is “the rule of law.” This means that a democratic system is a constitutional government in which the law is supreme, and all citizens and classes are equal before the law. According to the nineteenth-century British jurist Albert Venn Dicey, the objective of this principle, the rule of law, was to substitute “a government of laws” for a “government of men.” The rule of law is not a new value: The Romans provided the foundations of the rule of law and limited government in the West, and in fact the rule of law in Arabic-Islamic civilization antedated the Western
principle. There is more than a century between the emergence of this principle in the Islamic state in the seventh and eighth centuries and its recent manifestation in the thought of seventeenth- and eighteenth-century liberal thinkers and, later, in the democratic systems in western Europe and North America.

A democratic government is also a government in which all citizens, rather than one autocratic leader or a few people, have the right and opportunity to participate in the decision-making process. In a democratic system, the people are the ultimate source of authority, and the authority of the majority is limited by law (a written or unwritten constitution) as well as institutional means (such as separated and shared powers, checks and balances, and leadership succession through frequent and fairly conducted elections) so that the rights of individuals and minorities are protected. This form of government exists in western Europe, North America, Australia, New Zealand, Japan, and other regions and countries.

STRUCTURE AND FUNCTIONS OF MODERN DEMOCRATIC GOVERNMENT

The constitutions of modern democratic governments are the main mechanisms by which the principles of constitutional democracy can be enacted into specific institutions and procedures. On the practical level, modern democratic governments can be classified according to the basis of the institutional organization of the political executive body and the relationship between executive and legislative bodies into parliamentary, presidential, and semipresidential systems.

The executive power is composed of two organs in parliamentary governments. First is the head of the state, who is often a monarch or a president. Second, the government, which includes the head of government (called the prime minister, or chancellor) and the council of ministers, or the cabinet. The head of state is an inherited or elected figurehead with minor and ceremonial duties. He or she may have reserve authority (either by convention or by constitutional rule) that is usable in a crisis. Such authority, however, is usually exercised upon the advice and endorsement of the prime minister. The prime minister and the ministers of the cabinet are usually members of the parliament. The leader of the leading party (or group of parties) in the parliament is often appointed to be the prime minister. The government depends on the support of the parliament. Either the entire cabinet or single members can be removed by the parliament through a vote of no confidence. In turn, the executive body can dissolve the parliament and call for new elections. Thus, there is no clear-cut separation between the executive and legislative powers. The origins of this system go back to the British political system. The system also exists in many other democratic countries such as Spain, Japan, Sweden, Canada, and Australia.

In a presidential government, the executive organ, the president, is elected independent of the legislative institution. The president is both head of state and head of government, and there is sharp separation between the executive president and the legislature. Thus, the president is not a member, nor can he or she propose bills. Most importantly, the president cannot be removed by a vote of no confidence or any other political procedures. The president is elected for office for a fixed term and heads most of the agencies charged with executive functions such as enforcing and administering acts of the legislature. The president appoints a group of assistants (known as a cabinet) as heads of the executive departments and supervisors of the administrative agencies. This system of governing originated in the United States. Other countries with presidential systems include Indonesia, the Philippines, Mexico, and most countries in South America.

A semipresidential government is a system that has a cabinet and a president who both have substantial executive duties. This system differs from the parliamentary government because it has an elected president who is assigned substantial duties. Moreover, a semipresidential government differs from the presidential one in that it has a prime minister and a cabinet who are dependent on the support of the legislature. As in the parliamentary government, the cabinet, or a single minister, can be removed by a vote of no confidence in the parliament, and the president can dissolve the legislative assembly. France, Finland, Portugal, Romania, Taiwan, and Ukraine have semipresidential systems.

LEVELS OF GOVERNMENT

Modern states may be also classified according to the distribution of power at different levels of government into two main systems: unitary and federal. A unitary state is a state where the ultimate authority lies exclusively with a central government that controls central and local affairs. In such a system, local and regional authorities may make and implement policies, but they must have the permission of the central government. This form of government has emerged in former monarchies and empires such as France, Britain, and Japan. It also exists in countries with no ethnic divisions, such as the Scandinavian states, Egypt, and Turkey. The other form is a federal state, where political power is constitutionally shared between a federal government and local governments of constituent states or provinces. The function of the federal government is to handle foreign affairs, defense relations, and some internal functions such as monetary affairs. The local governments
of the provinces or states usually handle education and law enforcement. The existence and functions of the provinces or states may be changed only by amending the constitution, a process that protects them from the federal power.

GOVERNMENT, COALITION

A coalition government exists when two or more political parties formally agree to share executive responsibility and cabinet posts. Proportional representation systems common among parliamentary democracies often produce election results in which no single party wins an absolute majority of seats in a legislature. Such situations yield incentives for parties to build alliances in order to form a new government; absent the emergence of a coalition, the country is left either with leadership that does not command majority support or with the necessity of calling new elections. In political systems that encourage government by coalition, votes do not directly determine the composition of a new government; rather, they only determine which political parties will sit in parliament. Once that initial issue is settled, elected representatives and party leaders negotiate from among a potentially huge number of party combinations and permutations in search of a winning majority. Postelection coalition building can take days, weeks, and even months to complete, with the result being capture by one party of the premiership and distribution across coalition members of important posts such as foreign affairs, finance, justice, and the like. Coalition government stands as an alternative model to majoritarian governance, the latter being characterized by winner-take-all “first-past-the-post” electoral systems that favor clear distinctions between winners and losers.

Coalition government is the subject of a voluminous literature within the political science discipline. As a system of governance, the multiparty coalition is studied most frequently in European democracies whose electoral rules provide for even a modicum of proportionality. Italy’s penchant for short-lived postwar coalition governments is notorious, as is Belgium’s complex process of managing a delicate linguistic divide through coalitions. The reluctance of postwar German electorates to grant power exclusively to a single party has meant that coalition government—sometimes matching the country’s two largest parties in the same “grand coalition”—has been the norm there. Beyond Europe, coalition government is a standard expectation of democratic process in such countries as Israel, India, and Japan.

Advocates of coalition government tout the model’s ability to forge compromise and cooperation, and they point to greater inclusiveness as an additional virtue. Political parties in coalitional systems are competitive, but the prospect of governing with one’s competitors after an election can moderate campaign rhetoric. Granting new or untested parties a share of executive power as junior coalition partners may likewise moderate political extremism. According to supporters of this institutional approach to democratic governance, policies emerging from multiparty coalition governments should have a better chance of societal acceptance and successful implementation because they are the products of compromise rather than the imposition of political will by a lone dominant party.

Detractors claim that coalition governments are prone to weakness and instability, and because they can blur lines of accountability their democratic credentials are sometimes called into question. Opponents also object to the possibility of governments that are little more than “coalitions of losers,” marked by parties and adversaries whose electoral scores have just dropped precipitously but who nonetheless join forces to cling to power and forestall their mutual demise.

GOVERNMENT, FEDERAL

The member states of confederations establish federal governments to concentrate power in a central authority while maintaining the independence of their own govern-
ments. Traditionally, the member states of confederations have established federal governments as a means of combining their military and economic resources in response to regional threats and rivalries at the same time as they faced deep-seated ethnic, linguistic, or religious barriers to further national integration. The precise institutional structure that most skillfully juggling those two different sets of demands was difficult to define in theory, much less establish in practice. Centripetal forces within a federal system could produce political conflict among the member states just as easily as centrifugal forces could. Tudor England and the Holy Roman Empire exemplified those two tendencies.

The United States presents a somewhat unique case because at the time the federal government was established its member states were not divided along deep-seated ethnic, linguistic, or religious lines, nor had they enjoyed an independent existence before the establishment of the confederation. The framers of the U.S. Constitution generally agreed on the need to create a stronger federal government than had existed under the Articles of Confederation, but they differed on how much to strengthen it. Surprisingly, convention debates over specific powers were rare, except when they engaged existing interstate cleavages. In particular, the convention debate over a federal commerce power, including the power to regulate the slave trade, was heated because it engaged a number of interstate cleavages, between northern and southern states, between upper-South and lower-South states, between New England and mid-Atlantic states, and between commercial and agrarian states. However, in general the sense of the convention was to strengthen the federal government so that it was structured less like traditional federal governments and more like the national governments of the western European powers, which the delegates viewed as the future military and commercial rivals to their newly independent nation. At the same time, they sought to retain the state governments as viable parts of a new federal system of government, if for no other reason than that the Constitution would not otherwise have been ratified.

HISTORICAL DEVELOPMENTS
After the formation of this new type of “half federal, half national” system in the United States, some federal systems have been patterned more on this new, U.S. model (Australia) and some have been patterned more on the traditional, confederal model (Nigeria). Other federal systems represent a hybrid of the two models (Germany) or are clearly transitional in character (Russia). The confederal model has tended to be the least stable, though the original reasons for adopting such a model probably explain its instability more than any flaws in the model itself. The interaction between cultural and institutional causes of political instability was apparent in the case of the former Yugoslavia. As the twenty-first century began, there were twenty-five federal nations in the world, ranging in size from India to St. Kitts and Nevis, with a total of approximately 40 percent of the world’s population.

In debating how much to strengthen the federal government, the framers of the U.S. Constitution weighed three separate standards of comparison: prior federal governments, including their own; the western European national governments; and the member-state governments. Similarly, social scientists debate how much the federal government has strengthened its administrative, fiscal, and coercive capacities over the last two centuries relative to each of those three standards of comparison. Generally, they conclude that the federal government has strengthened its capacities, dramatically, as measured against its own earlier permutations, the western European national governments, and the member-state governments. Revisionists then present the “glass half-full” case. They argue that the nineteenth-century federal government was not as weak as supposed, pointing to such developments as the Federalists’ establishment of a highly elastic fiscal-military, military-fiscal state during the 1790s, the bureaucratization of the post and land offices during the 1820s and 1830s, and the exponential expansion of military pensioners over the course of the whole century.

RECENT RESEARCH AND CONTEMPORARY PROBLEMS
One interesting area of recent research examines the ways that indigenous and slave populations affected, both negatively and positively, the development of the federal government. Another area of research explores the ways that governing authority has constantly shifted back and forth across the relatively porous constitutional boundaries between the federal and state governments to create and re-create Morton Grodzins’s (1966) “marble cake” system. A third area of research involves comparative studies of federal systems. The best of these studies not only distinguish federal systems in terms of their different constitutional, legal, and institutional structures but also analyze the fit between those structures and the underlying political culture.

Beginning in the last two decades of the twentieth century Americans have witnessed a reinvigorated debate among their political elites, especially Supreme Court justices, over the constitutional boundaries of their federal system. The significance of this debate, however, pales before the debates over the viability of federal systems as solutions to the deep-seated ethnic, linguistic, and religious divisions in the developing nations of the world as
many of these nations continue to struggle with the artificial national boundaries that were imposed on them by their European colonizers. Power sharing between various ethnic, linguistic, and religious groups has become the rhetoric of success in nations as diverse as Iraq and the Sudan. Still, even the process of adopting a mutually acceptable constitution has proven extremely difficult. The federal solution remains available as a way of attempting to translate the rhetoric of power sharing into reality, but it is hardly sufficient as a solution to the multiple challenges these nations face.

GOVERNMENT, UNITARY

The term unitary government refers to a constitutional arrangement by which ultimate political authority is held by the central government of a state. In this system sovereignty is vested in the central government alone.

A unitary state does not necessarily imply that only one level of government exists. In fact, unitary states often have multiple levels of government, and in those states political authority is divided across different territorial levels. Japan is an example of a unitary state. It has a central government and below that forty-seven prefectures and over three thousand municipal governments. France is another example of a state with a unitary government. What makes a state unitary is that the central government has ultimate power over the other geographic levels of government and determines what those governments do, how much money they may spend, the location of their boundaries, and whether they exist. In unitary states, therefore, local or regional governments exist alongside central governments, but their financial and political autonomy and even their right to exist are determined by the central government.

The United Kingdom traditionally has been a unitary state with power heavily centralized in London. In that system local governments exist but are created and controlled by central government statute. An example of that control occurred in 1986 when the Conservative government passed legislation to abolish the metropolitan level of government in many major cities, including London. Since 1997, under a Labour government, there has been a devolution of political power in the United Kingdom. Part of the process has been the establishment of a Scottish parliament and a Welsh assembly with independent authority over a range of policy decisions in those territories. Constitutionally, however, the United Kingdom remains a unitary state. The devolved administrations in Scotland and Wales were created by acts of Parliament and in theory could be abolished in the same fashion.

Unitary systems stand in direct contrast to federal political systems. A federal system is one in which two or more levels of government exist but those governmental levels have a constitutionally guaranteed right to exist and constitutionally guaranteed powers. Unlike a unitary system, neither level of government can be abolished or reformed without the consent of the other. In the United States, for example, the federal government cannot abolish California or reform its borders without the consent of California. Other examples of federal states are Australia, Canada, India, and Brazil.

Arguments in favor of a unitary system include the fact that it allows for consistency of policymaking and service delivery across the whole state, in contrast to the differences that frequently are found in federal states. This has the potential to create a strong sense of national identity within a state.

John B. Sutcliffe
GOVERNMENT, WORLD

The concept of world government refers to the institutional organization and administration of global affairs, including issues of peace and security, economics, the environment, and the potential constitution of a comprehensive international system of law and justice. In today’s international system, the United Nations (UN) most closely approximates the idea of an institutionalized world government. However, to the extent that the UN system does indeed represent a world government, it differs from state or domestic governments in that it possesses no centralized authority with the power to enforce its rule. Generally speaking, domestic governments have a clear vertical or hierarchical structure of authority, with clear rules delineating who has the final say concerning executive decision-making, legislation, jurisprudence, and law enforcement. The international system does not operate under such a clear chain of command. To reflect this distinction, the term “global governance” is often used in place of the concept of world government.

An alternative tradition also exists that understands world government in darker, more ambiguous terms. From this perspective, the concept of world government evokes the specter of global domination by a single national power, faceless bureaucracy, or conspiratorial group controlling world affairs from behind closed doors. Nationalists and libertarians see the potential evolution of a world government as a potentially totalitarian threat to liberty and national identity. And for centuries, conspiracy theorists have claimed secret societies such as the “Illuminati” or Freemasons are the true powers that orchestrate global politics. Today, some fear that private-sector networks of the international political and business elite—such as the Trilateral Commission or the World Economic Forum—pull the strings of the global economy, representing a pseudo world government beyond the reach of public accountability.

THE UNITED NATIONS AS WORLD GOVERNMENT

While the UN is structured like a typical domestic government with executive, legislative, and judicial branches, it does not function like one. For example, the General Assembly of the UN is not the primary legislative body of international law. Rather, international law has two recognized foundations independent of the UN system: interstate treaties and long-standing customs—and as a result, in comparison to domestic governments, lawmaking at the level of world government is decentralized. Treaties are the most common way in which international rules are made. They involve the mutual agreement by two or more states to regulate behavior according to predetermined limits. The Geneva Conventions represent a series of such treaties. Customary laws, on the other hand—for example, the recognized freedom of the high seas—develop over time as a consequence of accepted long-standing conduct in international relations. Whereas treaty-based laws only regulate signatories, customary laws are held to be universal. To be effective, however, most international rules must be incorporated into domestic law by domestic legislators—thus the common requirement that national legislative bodies ratify international treaties. In the United States this is the responsibility of the Senate.

Considered as a form of world government, the UN also has very little independent enforcement power beyond threats of force issued by the Security Council. As a result, the authority of the UN depends upon either the willful compliance of member states or the force of a few dominant military and economic powers. For example, the International Court of Justice, representing the primary judicial institution of the UN system—and otherwise known as the World Court—was established to settle legal disputes between member states, and to issue advisory opinions if requested by other UN organs, such as the Security Council or the General Assembly. The statute of the International Court of Justice is part of the UN Charter, yet the enforcement of its decisions is generally dependent upon member-states’ willingness to comply. No state may be sued before the Court without accepting its jurisdiction over the particular case beforehand. Thus the more powerful a state, the more difficult it is to enforce decisions against it. The record of the United States is particularly poor in this regard. In 1986 the Court ruled against it in a case regarding the mining of Nicaraguan waters. The United States refused to recognize the process, and Nicaragua was powerless to appeal.

THE DEVELOPMENT OF INTERNATIONAL LAW

In fact, rather than referring to the international system as a present-day world government, it is more common to refer to international law as representing only the potential roots of a possible future world government. The modern rise of international law can be traced back to the Peace of Westphalia of 1648, which ended the Thirty Years’ War in part by recognizing the right of territorial sovereignty in interstate affairs. What came to be known as the Westphalian order is defined by two principles: state territoriality—the international recognition of well-defined borders—and the right to nonintervention in domestic affairs. The Westphalian order placed the independent nation-state at the center of the international system at the expense of larger supranational authorities such as the Holy Roman Empire or the Roman Catholic Church. Nonetheless, international law constituted only a minimal system of coexistence, and military force remained the pri-
mary mechanism for the settlement of conflict. The early nineteenth century witnessed the formation of the Concert of Europe—a balance of power arrangement with the goal of establishing security on the continent in the wake of the Napoleonic wars. Yet it was not until the end of World War I (1914–1918) and the founding of the League of Nations that the first systemic international organization was formed with the purpose of avoiding war altogether. And it was not until the close of World War II (1939–1945) that the formation of the United Nations, and the establishment of the International Military Tribunal for the Punishment of War Criminals, made aggressive war an internationally recognized crime.

After World War II, international law entered a new stage represented by the ban on the use of force and the elevation of human rights to the status of international law through the Universal Declaration of Human Rights. Historically, the subjects of international law had always been groups or collective actors, principally states. But with the rise of human rights and war crimes legislation more and more international law came to refer directly to the individual person, independent of particular group membership. With this development some understand international law to be following a trajectory that points away from the statist Westphalian model of international relations toward a universalist, cosmopolitan model of world government.

Most international law, however, remained state- or group-based well into the start of the twenty-first century. Many late-twentieth century developments do, however, point toward the coexistence of an alternative cosmopolitan model. For example, the International Criminal Court (ICC) points toward the development of an international system of justice in which individuals could claim to be citizens of the world subject to a single law executed by a single world government. Thus one might imagine a future world government as taking form around such a notion of universal citizenship. The ICC was founded in 1998 to prosecute perpetrators of the most heinous crimes recognized by the entire international community, including “genocide” and “crimes against humanity.” However, important obstacles to its success remain: Not all countries immediately recognized its authority, subsequently undermining its claim to universality; most important, the United States disputed its mandate, claimed special exemption from its jurisdiction, and pressured other countries—especially its aid recipients—to do the same. Similarly, other trends suggest that the decentralized structure of the international system could just as easily develop away from the consolidation of a coherent world government. For example, in the early years of the twenty-first century, international regulation was increasingly the product of private-public partnerships, resulting in a pluralization of rule-making structures rather than their institutional concentration.

GOVERNMENTALITY

The term governmentality was coined by the French philosopher and historian Michel Foucault (1926–1984). Foucault’s gouvernementalité was derived from the French word gouvernemental meaning “concerning government.” Foucault introduced the notion in his lectures of 1978 and 1979 at the Collège de France as a guiding principle in his “genealogy of the modern state” (Foucault 2004a, 2004b) illustrating his working hypothesis on the reciprocal constitution of technologies of power and political rationalities. Also, Foucault uses the notion of government in a sense geared strongly to the older meaning of the term, stressing the close link between forms of power and processes of subjectification. He demonstrates that in addition to the management by the state or the administration, government in the past also signified problems of self-control, guidance for the family, management of the household, or directing the soul. For this reason, Foucault defines government as “the conduct of conduct” and thus as a term that ranges from “governing the self” to “governing others” (Foucault 1982, pp. 220–221).

Foucault’s lectures trace the genealogy of governmentality from classical Greek and Roman days via the notion of state reason and the science of the police in early modernity through to liberal and neoliberal forms of government. While Foucault’s analytics of government remained more a fragmentary sketch than an elaborated theory, it has nevertheless inspired many studies in the social sciences and historical investigations. Especially in Great Britain, Australia, Canada, and the United States, scholars have sought to refine and extend Foucault’s work for a critical analysis of political technologies and governmental rationalities in contemporary societies.
These “studies of governmentality” have focused on the shift from the Keynesian welfare state toward the so-called free market policies in Western democracies and the rise of neoliberal political programs. The concept of governmentality offers two important theoretical advantages for this line of investigation. First, power relations are not restricted to the government of the state but include all forms of directing and guiding individuals and collectives in civil society and in the economic sphere. According to this theoretical perspective, the differences between state and society, politics and economy, the private and the public sphere do not function as universal foundations or essential borderlines, but as elements and effects of technologies of government that could be studied and critically assessed (see Foucault 1991, p. 103). Secondly, the liberal polarity of subjectivity and power ceases to be plausible. From the perspective of governmentality, government refers to a continuum, which extends from political government right through to forms of self-regulation. This theoretical stance allows for a more complex analysis of neoliberal forms of government that feature not only direct intervention by political authorities and empowered state agencies, but also develop indirect techniques for guiding and controlling individuals.

GRAMEEN BANK

The genesis of Grameen Bank (GB) can be traced back to 1974, when Mohammed Yunus, a professor in Chittagong University, loaned the equivalent of $27 to forty-two indebted residents of Jobra, a village in Bangladesh. Witnessing the grinding poverty and famine conditions, Yunus and his students conducted surveys and discovered the critical significance of credit for breaking out of the proverbial poverty trap. The distinctive feature of these loans was the absence of any collateral. The success of the experiment was almost immediate and led to the formal establishment of the GB on October 2, 1983, as a semiprivate institution to help alleviate poverty in rural Bangladesh. The word Grameen comes from the Bengali word gram, meaning “village.” The 2006 Nobel Peace Prize was awarded to Yunus and the GB, and today the bank is among the most famous nongovernmental organizations (NGOs) in the world.

Mohammed Yunus was born on June 28, 1940, in the port city of Chittagong, Bangladesh. His father was a goldsmith and his upbringing was comfortable. He was a successful entrepreneur starting a new family business, which he gave up when he received a Fulbright grant in 1965 to study economics at Vanderbilt University. After completing his PhD he taught briefly at Middle Tennessee State University (MTSU). The 1971 civil war and birth of the newly independent Bangladesh convinced him to return home. He first joined the planning commission in Dhaka, but soon returned to academia as the head of the economics program at Chittagong University. From this campus, he studied the economic lives of the poor and came up with the idea of the GB.

Yunus realized that the skilled poor could substantially raise their incomes and standard of living if they could bypass the middleman or the village moneylender, so he focused on how to make institutional credit available to the poor. Established banks had no interest in poor borrowers because the transaction cost of dealing with low-income customers in villages was high, and lending to them would violate the cardinal rule of banking—to lend only against valuable assets, or “collateral.” In his Nobel lecture, Yunus recalled, “I was shocked to discover a woman in the village borrowing less than a dollar from the moneylender on the condition that he would have the exclusive right to buy all she produces at the price he decides. This, to me, was a way of recruiting slave labor” (Yunus 2006).

Gradually, through trial and error and with the help of a dedicated group of students, Yunus developed the concept of a new type of banker who would visit poor rural customers in their homes and workplaces. The small loans are given only to the very poor—mostly women—who are disciplined and ambitious, with ideas for small (micro-) businesses, and successful in joining a team of four. After training, the team member with the best business model receives a micro loan, with the first installment to be paid the following week. Only when the first bor-
rower has substantially returned her loan can the other team members have their projects financed. The average loan is roughly $200 at 16 percent annually. Given the weekly returns, the effective annual interest rates are in the range of 20 to 30 percent, which may sound high, but they are significantly below the rates charged by village moneylenders, which are often around 120 percent annually. The bank offers additional products for its members—home loans, compulsory savings, disaster funds, life insurance, loans to beggars, and so on. The housing loan program has helped construct 640,000 new sturdy homes for its customers. In 1995 the bank stopped accepting donor funds, and today the bank is entirely self-financed and self-sustaining. According to internal studies, 58 percent of its clients have crossed the poverty line.

The Grameen Bank was created by a special presidential proclamation, which makes it a unique institution. At first, the ownership split between government and members was 60:40, but this was later changed to 25:75 in favor of the members or borrowers. The bank has given over $5.7 billion in micro loans since its inception to more than 7 million clients across 73,000 villages in Bangladesh (and with an average of five members in a Bangladeshi household, this amounts to a potential impact on 35 million citizens). A significant percentage of the members (97%) are women, and the loan repayment rate is an impressive 98 percent. As of 2007, the bank has 2,226 branches all over the country. The model with some variations has spread across the world, and can be found in communities in Europe, Latin America, and North America. According to one estimate, today more than 60 million poor worldwide have access to microfinance. The Grameen Bank is a shining instance of the success of idealistic ventures in the struggle against poverty.

GRAMSCI, ANTONIO
1891–1937

Antonio Gramsci counts among the most influential thinkers of the Left in the twentieth century. Born to a family of modest means in Caligari, Sardinia, Italy, Gramsci’s early life was characterized by poverty, and for most of his life he suffered from poor health, which was worsened by his long imprisonment in fascist Italy. He died in 1937 after more than ten years in prison.

LIFE

In addition to poverty and work to support his family, Gramsci’s early years in Sardinia introduced him to socialist politics, as well as to the writings of prominent Italian thinkers of his time, including Gaetano Salvemini (1873–1957), Benedetto Croce (1866–1952), Giuseppe Prezzolini (1882–1982), and Pilade Cecchi, in addition to becoming introduced to the writings of Karl Marx (1818–1883). The beginnings of Gramsci’s entry into the larger spheres of Italian political and intellectual life can roughly be dated to the years 1911 and 1912, when after obtaining a scholarship to attend the University of Turin, he immersed himself in the study of linguistics, philosophy, and literature, and also met a number of individuals who were to exercise a profound impact on his life, notably the leaders of the future Italian Communist Party (PCI), Palmiro Togliatti (1893–1964) and Angelo Tasca (1892–1960), as well as such intellectuals as Matteo Bartoli (1873–1946) and Umberto Cosmo (1868–1944).

His early academic promise notwithstanding, Gramsci dedicated much of his time after 1915 to journalism, becoming one of the most effective public voices of the Italian Socialist Party, from whose split the PCI was born with Gramsci’s active participation in 1921. In those years he wrote regular columns for the Turin edition of the newspaper Avanti! (Forward!), and in 1919 he co-founded L’Ordine Nuovo (The New Order), which became an influential review. During those years Gramsci was constantly active in workers’ militant organizing, and devoted much time to the factory council movement, in addition to giving talks to workers’ study groups on historical revolutionary experiences, including the French Revolution and the Paris Commune, as well as on literature and Marxist philosophy.

Following the split that produced the PCI in 1921, Gramsci lived for over a year in Moscow (1922–1923) as an Italian delegate to the Communist International (Comintern), returning to Italy after his election to the Chamber of Deputies in 1924 gave him temporary immunity from arrest. During that period he also became the general secretary of the PCI. His writings at that point show concern about the main issues of the moment,
including the rise of Joseph Stalin (1879–1953) in the Soviet Union and the elimination of the opposition in the Comintern, as well as the “southern question” in Italy—namely the less developed status of southern Italy, its status as a colonial periphery of the north, and the need of the communist party for a distinct strategy to mobilize the agrarian population—and the relationship between workers and intellectuals.

THOUGHT

The bulk of Gramsci’s intellectual output, however, is contained in his *Prison Notebooks*, a large compendium of essays, commentaries, and letters written during his internment, which began to be published in piecemeal fashion by the PCI after World War II (1939–1945). It is these writings that reveal Gramsci’s distinctive contribution to social theory and Left analysis, even though they are colored by a certain cryptic style designed to maneuver around issues sensitive to prison censors. The most significant innovations in these writings include Gramsci’s thesis on hegemony, the role of intellectuals, and the status of the peasantry in Left analysis.

The notion of hegemony, in particular, was developed by Gramsci as a way to account for a deficiency in the revolutionary character of the working class, as well as to amend the economic determinism that had plagued Marxist analysis. In some ways, “hegemony” was Gramsci’s way of elaborating the actual working out of Marx’s famous dictum, “the ideas of the ruling class are always the ruling ideas.” In Gramsci’s formulation, hegemony accounts for how domination is exercised apart from coercion and force. The dominated classes or groups have their own reasons for accepting the ideas of a ruling class or elite, and such reasons are the ground for the spontaneous consent given to a dominant ideology by classes that are dominated by it.

This concept has obvious affinities to other terms used in the social sciences, such as unquestioned “common sense.” However, contrary to appearances, hegemony, even if taken as “common sense,” is not stable. It is liable to break down as the subordinated groups develop alternative ways of seeing the world, and as crises within established systems create room for precisely the emergence of alternative hegemonies. The key to this kind of transformation consists thus of cultural and political work in society, rather than simply revolutionary action. This is precisely what Gramsci meant by “war of position” (the long, patient work in civil society oriented to combating established hegemony), to be distinguished from “war of maneuver” (the revolutionary takeover in a society where domination is not complemented by hegemonic sway over society at large).

It was such an orientation toward questions of culture, consciousness, and active agency that also highlighted for Gramsci the role of intellectuals. He saw that intellectuals are crucial in articulating and disseminating the outlooks of the classes for which they speak, in a way that goes beyond the simple expression of economic interests. For the working class, an intellectual who fulfilled that role was not confined in Gramsci’s thought to a stratum of educated, revolutionary elite. Rather, the “organic intellectual” could also be a lay person whose expression of the specific ideology of his class originates out of his actual working life. This conception arises out of Gramsci’s argument that all individuals are intellectual in the sense of having and using an intellect, though not all are intellectuals in terms of their formal social role.

Finally, unlike many intellectuals on the left who ignored the peasantry while highlighting the role of the working class, Gramsci emphasized the need to address the “southern question,” especially in countries like Italy (and Russia) where the peasantry comprised a large proportion of the population. His cryptic references to the “subaltern” encapsulate this orientation, and suggest the need for the party to assimilate the work of the organic intellectuals of segments of the population that it had ignored.

These various dimensions of Gramsci’s outlook have insured him great influence over twentieth-century thought. Those looking for sources of inspiration in Marxist thought beyond economic determinism have turned to his work, as have media scholars who were interested in exploring how certain ideas disseminate more broadly than others.

GRANT, ULYSSES S.
1822–1885
Born as Hiram Ulysses Grant on April 27, 1822, at Point Pleasant, Ohio, the son of Jesse Root and Hannah Simpson Grant, Grant grew up in nearby Georgetown. In 1839 he entered the U.S. Military Academy at West Point, graduating in the middle of his class in 1843; it was at this time that he became Ulysses S. Grant, a result of a West Point clerical error. During the Mexican-American War (1846–1848), he saw action in several battles, despite the fact that he served as quartermaster and commissary officer for his regiment. Marrying Julia Dent in 1848, he found peacetime military service frustrating professionally and personally, and resigned his commission as captain in 1854. Over the next seven years, Grant struggled to provide for his family, which eventually included four children. A combination of bad luck, uncertain health, and the impact of the economic panic of 1857 left him impoverished before he took a position at his father’s general store in Galena, Illinois, in 1860. With the outbreak of the Civil War (1861–1865) the following year, he offered his services, eventually securing a colonel’s commission; before long he found himself a brigadier general, courtesy of the influence of his hometown congressman.

In 1861 Grant led U.S. forces southward into Kentucky and Missouri, securing Paducah in September. The following year, forces under his command, aided by a gunboat flotilla, captured Fort Henry (February 6, 1862) and Fort Donelson (February 16, 1862), along with some twelve thousand Confederate soldiers. Two months later, he fended off a Confederate attack at Shiloh, Tennessee (April 6–7, 1862), although the high losses he suffered and his lack of preparedness brought him under heavy criticism.

Late in the fall of 1862, after fending off several Confederate efforts to retake western Tennessee, Grant began planning to capture Vicksburg, Mississippi, the major remaining Confederate stronghold along the Mississippi River. After several abortive efforts, he took the city on July 4, 1863, following a campaign of marching and fighting that kept superior enemy forces off balance. The victory secured his hold on an important command: In November he scored another triumph at Chattanooga, Tennessee, a victory that paved the way for President Abraham Lincoln (1809–1865) to elevate him to overall command of the armies of the United States in 1864. In less than fourteen months from assuming command, Grant devised the grand strategy and coordinated the campaigns that led to the collapse of the Confederacy. He took charge of the forces opposing the Confederacy’s leading general, Robert E. Lee (1807–1870), and in some six weeks of bloody campaigning forced Lee back to defend the Confederate capital at Richmond, Virginia. Holding Lee in check while other Union armies triumphed (as did Lincoln in his reelection bid), Grant pushed Lee out of Richmond at the beginning of April, tracked him down, and forced him to surrender what remained of his army on April 9, 1865.

Immediately after the war, Grant urged reconciliation between North and South, but he quickly came to oppose white supremacist violence and to support recognizing black civil and eventually political rights. His popularity as a war hero made him an ideal presidential candidate for the Republican Party in 1868: His triumph came in the first election in which black Americans voted in large numbers, enough to secure Grant’s majority in the popular vote. Having run for the presidency in the belief that only he could stave off a Democratic resurgence and preserve the fruits of military victory, Grant unsuccessfully attempted to balance sectional reconciliation with federal protection of black equality before the law.

During Grant’s first term, the former Confederate states completed their return to civil government, while the ratification of the Fifteenth Amendment appeared to safeguard black voting. His efforts to subdue terrorist groups such as the Ku Klux Klan enjoyed initial success, although eventually a combination of white supremacist persistence, eroding public support, adverse court decisions, and inadequate institutional foundations led to the recapture of the former Confederate states by the Democratic Party. Although Grant oversaw the establishment of a stable deflationary monetary policy and a peaceful settlement of outstanding issues with Great Britain, his efforts to build a political base through patronage to help him pass his agenda, especially the attempted annexation of the Dominican Republic, only spurred greater opposition within his own party. Eventually, these opponents formed the short-lived Liberal Republican movement, which unsuccessfully tried to thwart Grant’s bid for reelection in 1872.

The onset of economic depression and the revelation of corruption within the administration marred Grant’s second term, as did the collapse of his peace policy toward Native Americans. Leaving office in 1877 after playing a critical role in resolving the disputed election of 1876, Grant took a trip around the world, returning to fail in a
bid for the 1880 Republican presidential nomination. Moving to Wall Street, Grant tried his hand at business once more, only to be impoverished when he became the victim of a swindler. Soon thereafter, he learned he had throat cancer. In order to provide for his family, Grant commenced writing his autobiography, completing the manuscript, widely praised as a masterpiece, only days before his death at Mount McGregor, New York, on July 23, 1885. He was buried in New York City; in 1897 his remains were reinterred in a massive tomb overlooking the Hudson River.

As a general, Grant displayed a doggedness and aggressiveness that sometimes overshadowed his ability to plan and conduct major campaigns and coordinate his forces, skills not evident in his predecessors in high command. Critics claim that he was a blundering bloody butcher, but the indictment does not stand up under examination. He also displayed a shrewd willingness to cooperate with his civil superiors and came to embrace both emancipation and the waging of hard war as keys to victory. As such, he has been cited as a model for military leadership and business management, something of an irony given his failures in business. Assessments of his presidency as a flat failure have given way to a more balanced view that takes into account the difficult problems Grant faced and gives him due credit for his successes and for exhibiting some political skill.

SEE *Grutter Decision*.

**GRAUNT, JOHN**

1620–1674

John Graunt is recognized as the father of demography for his systematic yet critical use of population data to investigate demographic processes. He originated a number of demographic techniques and demonstrated a healthy skepticism of his own data.

Graunt was born in England in 1620. He was the son of a draper and, after completing his apprenticeship, he inherited his father’s business. Graunt acquired some degree of wealth and prestige and rose through the ranks of civil service, although he was not among the educated class of his day.

As a pastime, Graunt studied the Bills of Mortality—birth and death registers published weekly and annually in the *London Times* throughout the seventeenth century. Birth data was collected from christenings; mortality data was collected by older women, called *searchers*, who were paid to inquire about cause of death from family and physicians. Graunt’s *Natural and Political Observations on the Bills of Mortality*, which appeared around 1662, explored many demographic questions. His empirical investigation revealed that females tended to have a longer lifespan than males, that London was growing through internal migration from the country, and that the population of London was actually much smaller (around 460,000 people) than commonly asserted (estimates ranged up to seven million).

Graunt also formulated a number of methods that continue to be used by demographers today. He expressed the number of male births relative to female births as a ratio, creating what has come to be known as the *sex ratio at birth*. He estimated a *doubling time* for the growth of the city of London. In addition, Graunt observed that mortality varies by age. This insight led him to develop the first *life table*—a table that follows a virtual population of one hundred people through the age-specific mortality rates of the actual population. Edmund Halley (1656–1742) later perfected the life table and gave it its actuarial application.

One of Graunt’s most important methodological contributions was a skepticism of his own data. Graunt was concerned with unavailable data, poorly defined categories, misspecification of the cause of death, and underreporting. He discussed at length the possibility of searchers being inaccurate, bribed, or drunk at the time of inquiry.

Graunt’s work also made the critical contribution of substantive interpretation. Previously, the Royal Statistical Society’s official goal was merely to gather data, not to interpret it. The Society claimed that “threshing out” the implications of data should be left to the court (i.e., politicians), a position that protected the Society from appearing partisan, but discouraged demographic research.

Late in life, Graunt converted to Catholicism. In the politically and religiously charged atmosphere of England at the time, his conversion had tragic consequences. He
was forced to resign from his positions in civil service. The Great Fire of London in 1666 destroyed his home—a setback from which he never recovered. He lived out his last years with the financial help of his friend William Petty (1623–1687). Graunt died in 1674 in such poverty that the Draper Society awarded his widow £4 annually for her upkeep.

GREAT DEPRESSION
Between 1929 and 1933 the world economy collapsed. In country after country, although not in all, prices fell, output shrank, and unemployment soared. In the United States the rate of unemployment reached 25 percent of the labor force, in the United Kingdom 16 percent, and in Germany a staggering 30 percent. These rates are only roughly comparable across countries and with twenty-first century unemployment rates because of different definitions of unemployment and methods of collection; nevertheless, they show the extremity of the crisis. The recovery, moreover, was slow and in some countries incomplete. In 1938 the rate of unemployment was still at double-digit levels in the United States and the United Kingdom, although thanks to rearmament it was considerably lower in Germany. A number of previous depressions were extremely painful, but none was as deep or lasted as long. There were many recessions that came after, but none could begin to compare in terms of prolonged industrial stagnation and high unemployment. The consequences stemming from the Great Depression for economies and polities throughout the world were profound. The early appearance of depression in the United States and the crucial role of the United States in world trade make it important to consider the U.S. case in some detail.

THE GREAT DEPRESSION IN THE UNITED STATES
There had been severe depression in the United States before the 1930s. The most similar occurred in the 1890s. Indeed, the sequence of events in the 1890s foreshadowed what was to happen in the 1930s in some detail. Prices of stocks began to decline in January 1893, and a crash came in May and June after the failure of several well-regarded firms. The market continued to decline, and at its low point in 1896 had lost 30 percent of its value. The decline in the stock market was associated with a sharp contraction in economic activity. A banking panic intensified the contraction. There seem to have been two sources for the panic. First, fears that the United States would leave the gold standard prompted by the growing strength of the free silver movement led to withdrawals of gold from New York. In addition, a wave of bank failures in the South and West produced by low agricultural prices also undermined confidence in the banking system. Runs on banks spread throughout the country and the crisis ended with a general restriction of the conversion of bank notes and deposits into gold. The money supply fell, the economy slowed, bank and business failures multiplied, and unemployment rose. Although a recovery began in June 1894, the recovery was slow and uneven. By 1897 one-third of the railroad mileage in the United States was in receivership. It took until 1898 for the stock market to match its 1893 peak, and for annual real gross domestic product (GDP) per capita to match its 1892 level.

During the early 1930s events unfolded in a similar fashion. There were few signs in 1929, however, that a Great Depression was on the horizon. There had been a severe contraction in 1920–1921, but the economy had recovered quickly. There were minor contractions in 1923–1924 and 1926–1927, and the agricultural sector had struggled during the 1920s, but overall the economy prospered after the 1920–1921 recession. In 1929 unemployment in the United States was just 3.2 percent of the labor force; in many ways it was a vintage year.

The stock market boomed in the late 1920s and reached a peak in 1929; prices rose nearly 2.5 times between 1927 and its peak in 1929. Economic historians
have long debated whether there was a bubble in the market in the late 1920s, meaning that prices of shares had risen more rapidly than “fundamentals.” Research conducted in 1993 by Peter Rappoport and Eugene White and other late-twentieth-century views have strengthened the case for a bubble. They have shown that many well-informed investors doubted the long-run viability of prevailing prices. There were undoubtedly, however, many other investors who believed that the economy had entered a so-called New Age, as was said at the time, in which scientific and technical research would produce rising real incomes, rising profits, and an eventual end to poverty.

The crash of the stock market in the fall of 1929 was partly a reflection of the state of the economy—a recession was already under way—but the crash also intensified the slowdown by undermining confidence in the economic future. The major impact of the crash, as shown by Christina Romer in her 1990 work, was to slow the sale of consumer durables. The crash may also have influenced markets around the world by forcing investors to reassess their optimistic view of the future. In any case, the stock markets in most other industrial countries after having risen in the 1920s also fell to very low levels in the first half of the 1930s. The U.S. market lost two-thirds of its value by 1933, the German market (which had peaked before the American market) lost one half, and the British market, which did somewhat better, lost one-fifth.

The collapse of the American banking system then intensified the contraction. There were repeated waves of bank failures between 1930 and 1933 produced by the economic contraction, by the decline in prices, especially in the agricultural sector, and perhaps by a contagion of fear. As people withdrew their cash from banks to protect their wealth, and as banks increased their reserves to prepare for runs, the stock of money shrank. The collapse of the American banking system reflected a number of unique circumstances. First, laws that prevented banks based in one state from establishing branches in other states, and sometimes from establishing additional branches within a state, had created a system characterized by thousands of small independent banks. In contrast, most other countries had systems dominated by a few large banks with branches. In Canada where the system consisted of a small number of banks with head offices in Toronto or Montreal and branches throughout the country there were no bank failures. In addition, the young and inexperienced Federal Reserve System (it was established in 1913) proved incapable of taking the bold actions needed to end the crisis.

Many explanations have been put forward for the failure of the Federal Reserve to stem the tide of bank runs and closures. Milton Friedman and Anna J. Schwartz in their classic Monetary History of the United States (1963) stressed an internal political conflict between the Federal Reserve Board in Washington and the New York Federal Reserve Bank that paralyzed the system. A 2003 study by Allan Meltzer stresses adherence to economic doctrines that led the Federal Reserve to misinterpret the fall in nominal interest rates during the contraction. The Treasury bill rate fell from about 5 percent in May 1929 to .10 percent in September 1933. The Federal Reserve viewed low rates as proof that it had made liquidity abundant and that there was little more it could do to combat the depression. The bank failures, which were concentrated among smaller banks in rural areas, or in some cases larger banks that had engaged in questionable activities, the Federal Reserve regarded as a benign process that would result in a stronger banking system. From 1930 to 1933 about 9,000 banks in the United States suspended operation and the money supply fell by one-third.

During the interregnum between the election of President Franklin Roosevelt in November 1932 and his taking office in March 1933 the banking system underwent further turmoil. In state after state governors proclaimed “bank holidays” that prohibited or limited withdrawals from banks and brought the banking and economic system to a standstill. The purpose of the holidays was to protect the banks from panicky withdrawals, but the result was to disrupt commerce and increase fears that the system was collapsing. By the time Roosevelt took office virtually all of the banks in the United States were closed and perhaps one-quarter of the labor force was unemployed. Roosevelt addressed the situation boldly. Part of his response was to rally the spirits of the nation. In his famous first inaugural address he told the people that “the only thing we have to fear is fear itself.” His address also promised work for the unemployed and reforms of the banking system. The administration soon followed through. Public works programs, which focused on conservation in national parks and building infrastructure, were created to hire the unemployed. In the peak year of 1936 approximately 7 percent of the labor force was working in emergency relief programs.

The banking crisis was addressed in several ways. Banks were inspected and only “sound” banks were allowed to reopen. The process of inspection and phased reopening was largely cosmetic, but it appears to have calmed fears about the safety of the system. Deposit insurance was also instituted. In 1963 Milton Friedman and Ann Jacobson Schwartz argued that deposit insurance was important in ending the banking crisis and preventing a new eruption of bank failures by removing the fears that produced bank runs. Once depositors were insured by a federal agency they had no reason to withdraw their funds in cash when there was a rumor that the bank was in trouble. The number of bank failures in the United States
dropped drastically after the introduction of deposit insurance.

The recovery that began in 1933, although not without setbacks, was vigorous and prolonged. By the middle of 1937 industrial production was close to the 1929 average. Still, there was considerable concern about the pace of recovery and the level of the economy. After all, with normal economic growth the levels of industrial production and real output would have been above their 1929 levels in 1937. Unemployment, moreover, remained stubbornly high. With a few more years of continued growth the economy might well have recovered fully. However, another recession, the “recession within the depression,” hit the economy in 1937. By the trough in 1938 industrial production had fallen almost 60 percent and unemployment had risen once more. Mistakes in both fiscal and monetary policy contributed to the severity of the contraction, although the amounts contributed are disputed. The new Social Security system financed by a tax on wages was instituted in 1935, and the taxes were now put in place. The Federal Reserve, moreover, chose at this time to double the required reserve ratios of the banks. The main purpose of the increase was to prevent the reserves from being a factor in the future, to tie them down. The banks, however, were now accustomed to having a large margin of reserves above the required level and they appear to have cut their lending in order to rebuild this margin. The economic expansion that began in the summer of 1938, however, would last throughout the war and pull the economy completely out of the depression. Indeed, even before the United States entered the war as an active participant at the end of 1941, fiscal and monetary stimuli had done much to cure the depression.

THE DEPRESSION WIDENS

Most market-oriented countries, especially those that adhered to the gold standard, were affected by the Great Depression. One reason was the downward spiral of world trade. The economic decline in the United States hit hard at firms throughout the world that produced for the American market. As the depression spread from country to country, imports declined further.

The gold standard, to which most industrial countries adhered, provided another channel for the transmission of the Great Depression. The reputation of the gold standard had reached unchallenged heights during the period of expanding world trade before World War I. Most countries, with the exception of the United States, had abandoned the gold standard during the war to be free to print money to finance wartime expenditures. After the war, the gold standard had been reconstructed, but in a way that left it fragile. Most countries decided not to deflate their price levels back to prewar levels. Hence the nominal value of world trade relative to the amount of gold in reserve was much higher after the war than before. Under the gold standard orthodoxy of the day central banks were supposed to place maintenance of the gold standard above other priorities. If a country was losing gold because its exports had fallen faster than its imports, the central bank was supposed to raise interest rates to protect its gold reserve, even if this policy exacerbated the economic contraction. Countries that gained gold might have lowered their rates, but they were reluctant to do so because lower rates would put their gold reserves at risk.

The global transmission of information and opinion provided a third, hard to measure, but potentially important channel. The severe slide on the U.S. stock market and other stock markets focused attention throughout the rest of the world on factors that might produce a decline in local markets. Waves of bank failures in the United States and central Europe forced depositors throughout the rest of the world to raise questions about the safety of their own funds. Panic, in other words, did not respect international borders.

Although these transmission channels assured that the whole world was affected in some degree by the depression, the experience varied markedly from country to country, as even a few examples will illustrate. In Britain output fell from 1929 to 1932, but the fall was less than 6 percent. The recovery, moreover, seems to have started sooner in Britain than in the United States and the growth of output from 1932 to 1937 was extremely rapid. Unemployment, however, soared in 1929 to 1931 and remained stubbornly high for the remainder of the decade. Although Britain was becoming less dependent on exports, exports were still about 15 percent of national product. The fall in exports produced by the economic decline in the United States and other countries, therefore, probably explains a good deal of the decline in economic activity in Britain. In September 1931 Britain devalued the pound and left the gold standard. The recovery in Britain began soon after. Export growth produced by a cheaper pound does not seem to have played a prominent part in the recovery, but a more expansionary monetary policy permitted by leaving gold does seem to have played a role. On the whole it may be said that the British economy displayed surprising resiliency in the face of the loss of its export markets.

Germany, on the other hand, suffered one of the most catastrophic declines. A severe banking crisis hit Germany in July 1931, punctuated by the failure of the Darmstädter-und Nationalbank on July 13. The German crisis may have been provoked by the failure of the Credit Anstalt bank in Austria in May 1931 and the subsequent run on the Austrian shilling, although economists have debated these factors. Germany soon closed its banks in
an effort to stem the runs, and abandoned the gold standard. Germany, however, did not use the monetary freedom won by abandoning the commitment to gold to introduce expansionary policies. Between June 1930 and June 1933 the stock of money in Germany fell by nearly 40 percent. Prices and industrial production fell, and unemployment soared. Under the Nazis government spending, much of it for rearmament, and monetary expansion produced an extended economic boom that restored industrial production and full employment.

The experience of Japan where the depression was unusually mild has stimulated considerable interest. Unemployment rose mildly by Western standards between 1929 and 1933 and fell to 3.8 percent by 1938. Other indicators, such as the stock market, also rose between 1933 and 1938. Many observers have attributed this performance to the actions of Finance Minister Korekiyo Takahashi. In 1931 Takahashi introduced a stimulus package that included a major devaluation of the yen, interest rate cuts, and increases in government spending. The latter element of his package has led some observers to refer to Takahashi as a “Keynesian before Keynes.” Late twentieth-century research has challenged the notion that Takahashi was able to break completely free of the economic orthodoxies of the day, but the strong performance of the Japanese economy remains an important signpost for scholars attempting to understand the factors that determined the course of events in the 1930s.

THEORIES

The factors previously stressed, the collapse of the banking system in the early 1930s, and the policy mistakes by the Federal Reserve and other central banks are of most relevance to what has come to be called the monetarist interpretation of the Great Depression. Some economists writing in the 1930s, such as Jacob Viner and Laughlin Currie, developed this view, concluding that much of the trouble could have been avoided if the Federal Reserve and other central banks had acted wisely.

In the aftermath of the publication of John Maynard Keynes’ General Theory (1936), however, an alternative interpretation held sway. The Keynesians argued that the breakdown of the banking system, although disturbing, was mainly a consequence of the collapse of aggregate demand. The behavior of the Federal Reserve was at most a secondary problem. The Keynesians blamed the fall in aggregate demand on the failure of one or more categories of autonomous spending. At first, attention focused on investment; later attention shifted to consumption. The answer to the Great Depression was public works financed, if necessary, by borrowing. The New Deal in the United States had spent a great deal of money and run up highly controversial deficits; 1956 calculations by E. Cary Brown, however, showed that a number of factors, including cuts in spending at the state and local level, had offset the effects of New Deal spending. Fiscal policy had failed to return the economy to full employment, according to Brown, “not because it did not work, but because it was not tried” (1956, pp. 863–866).

Friedman and Schwartz’s Monetary History, which provided an extraordinarily detailed account of the effects of monetary policies during the 1930s and put the Great Depression into the broader context of American monetary history, returned the collapse of the banking system to center stage. Their interpretation was challenged in turn by Peter Temin in Did Monetary Forces Cause the Great Depression (1976) who defended the Keynesian interpretation. Subsequent work, however, continued to emphasize the banking crisis. The 1983 research of Ben Bernanke, who later became chair of the U.S. Federal Reserve, was particularly influential. Bernanke argued that the banking and financial crises had disrupted the ability of the banking system to act as an efficient financial intermediary. Even sound businesses found it hard to borrow when their customary lender had closed its doors and the assets they could offer as collateral to another lender had lost value. The Bernanke thesis not only explained why the contraction was severe, but also why it took so long for the economy to recover: It took time for financial markets to rebuild the relationships that had been sundered in the early 1930s.

Research that took a more global view of the Great Depression, such as Peter Temin’s 1989 work, reinforced the case for viewing monetary forces as decisive. Barry Eichengreen’s Golden Fetters (1992), one of the most influential statements of this view, stressed the role of the gold standard in transmitting the Depression and inhibiting recovery. Countries faced with balance of trade deficits because of declining exports should have maintained their stocks of money and aimed for internal price stability. Instead they often adopted contractionary policies aimed at stemming the outflow of gold. Those countries that abandoned the gold standard and undertook expansionary monetary policies recovered more rapidly than those who clung to gold. The examples provided by countries, such as Japan, which avoided trouble because they had never been on gold or quickly abandoned it were particularly telling.

In the twenty-first century economists have turned to formal models, such as dynamic computable general equilibrium models, to address macroeconomic questions, and have used these models to formulate and test ideas about the Great Depression. The 2002 and 2005 work of Harold Cole and Lee Ohanian has received considerable attention in both academic and mainstream circles. It is too early to say, however, whether this work will serve to
reinforce traditional interpretations of the Great Depression reached by other methods or produce entirely new interpretations. It is not too soon to predict, however, that the Great Depression will continue to attract the interest of scholars attempting to understand basic macroeconomic processes.

One cannot say for certain that another Great Depression is impossible, but important lessons have been learned and important changes made in the financial system that make a repetition highly unlikely. For example, it seems improbable that any modern central bank would allow a massive collapse of the banking system and deflation to proceed unabated as happened in a number of countries in the early 1930s.

GREAT SOCIETY, THE

The term *Great Society*, which refers to the set of domestic programs initiated by Lyndon B. Johnson, who became the U.S. president after the assassination of John F. Kennedy in 1963, was coined by Johnson’s speechwriter Richard N. Goodwin early in 1964. In an address during commencement exercises at the University of Michigan at Ann Arbor on May 22, Johnson used the term publicly for the first time. The new chief executive, eager to map out his own legislative agenda, challenged the American people to build a society “where progress is the servant of our needs,” a society “where old values and new visions are buried under unbridled growth,” a society that “rests on abundance and liberty for all,” a society that “demands an end to poverty and racial injustice.” Johnson identified the three places to begin the building of the Great Society—in the cities, in the countryside, and in the classrooms. He catalogued the social ills that needed to be corrected—urban decay, inadequate housing, poor transportation, environmental pollution, overburdened seashores, disappearing green fields, a poorly educated adult population, overcrowded classrooms, outdated curricula, unqualified teachers, and inadequate college funding. The far-thinking president envisioned a society where people are more concerned with the “quality of their goals” than the “quantity of their goods,” a glorious America where the meaning of people’s lives matches the
marvelous products of their labor (Public Papers of the Presidents of the United States, pp. 704–707).

Johnson, who came to Washington during the 1930s, modeled his domestic initiatives on Franklin D. Roosevelt’s New Deal, the policies implemented to combat the effects of the Great Depression. At the same time, the concept of the Great Society was meant to continue the legislative program begun by President Kennedy, called the New Frontier, and its implementation followed the same path.

The 1960s legislation, in contrast to the New Deal of the 1930s, was begun in a period of economic prosperity. After Johnson’s Ann Arbor speech, fourteen separate task forces comprised of government experts and university scholars were assembled to study all major aspects of American society. One task force addressed foreign affairs, and the rest tackled domestic policies concerning agriculture, economic recession, civil rights, education, economic efficiency, health, income maintenance, intergovernmental cooperation, natural resources, environmental pollution, preservation of natural beauty, transportation, and urban problems. During the 1964 presidential campaign, however, the proposed Great Society agenda, other than civil rights, was not widely discussed. Johnson’s popular vote majority of 61 percent, combined with the Democrats’ winning enough seats to control two-thirds of the House and Senate, set the stage for the subsequent passage of bills submitted to both chambers. Lingering public and congressional sympathy for the slain president’s program undoubtedly helped as well.

In late 1964 Johnson reviewed the task force reports submitted to the White House, and a number of recommendations were briefly mentioned in his State of the Union address on January 7, 1965. The president, now elected in his own right, confidently talked about the “beginning of the road to the Great Society” and summit meetings ahead with foreign heads of state, “where freedom from the wants of the body can help fulfill the needs of the spirit.” He sought opportunity for all, a just nation that would provide hospital care for the elderly under social security, eliminate poverty in the midst of plenty, assure civil and voting rights for blacks, and provide to immigrants the promise of America based on the work they could do and not where they were born. In 1965 eighty-seven bills were submitted to Congress by the new administration, eighty-four of which were signed by Johnson. With this legislation, in addition to the Civil Rights Act passed in 1964, the core of the Great Society was created.

**LEGISLATIVE ACTIONS**

It was in the areas of civil rights and economic assistance that the Great Society was most effective. The Civil Rights Act (1964) made employment discrimination and segregation in public accommodations—on the basis of race, color, religion, sex, or national origin—illegal. This legislation was followed by the Voting Rights Act (1965), which guaranteed minority voter registration and voting by restricting the use of literacy tests and poll taxes. The Immigration and Nationality Services Act (1965) did away with the national origin quotas put in place in 1924; this law opened the door to waves of Asian and Latin American immigrants, a pattern still apparent in the early twenty-first century. The 1968 Civil Rights Act outlawed discrimination in housing and granted constitutional protections to Native Americans living on reservations. Johnson’s so-called War on Poverty had its roots in the Economic Opportunity Act (1964), which established an Office of Economic Opportunity (OEO) to manage a variety of “community action” programs. The OEO was never meant to deal with poverty by raising welfare payments or guaranteeing wages, but to help the poor help themselves through education, job training, and community development. The Job Corps, Project Head Start, the Model Cities Program, the Neighborhood Youth Corps, Upward Bound, and VISTA were the most important new programs designed to assist poor people.

The Great Society also spawned well-known legislation in the areas of education and healthcare. The Elementary and Secondary Education Act (1965) provided significant federal aid to public education, and secured Head Start, originally a summer program, as a permanent component. Since education was a state and local matter, the federal government previously had refrained from assisting public schools for fear of violating the principle of “separation of powers.” The Higher Education Act (1965) raised federal aid to public and private universities, granted scholarships and low-interest loans to students, and set up a National Teachers Corps. The Bilingual Education Act (1968) helped local school districts address the English-language needs of minority children. Medicare and Medicaid, today the bedrock of the U.S. healthcare system, had their origins in the Social Security Act of 1965. Initially bitterly opposed by the American Medical Association, these publicly funded programs that covered hospital costs and doctors’ fees have been indispensable to older Americans, welfare recipients, and low-income families.

Legislative actions in the areas of culture, transportation, consumer protection, and the environment are likewise the direct result of President Johnson’s vision for a better America. The National Foundation on the Arts and Humanities Act (1965) created two separate federal agencies for the funding of artistic and humanistic pursuits to counterbalance the emphasis given to scientific endeavors. The Urban Mass Transportation Act (1964) provided hundreds of millions of dollars in matching funds to cities.
for public and private rail projects, and the Highway Safety Act (1966) was enacted to protect motorists from unsafe roads and vehicles. American consumers benefited from a number of laws such as the Child Safety Act (1966), the Flammable Fabrics Act (1967), the Wholesale Meat Act (1967), and the Truth-in-Lending Act (1968).

More than any of the other sets of laws associated with the Great Society, the civil rights legislation of the 1960s stirred public controversy, which has continued for four decades. Johnson issued in 1965, and later expanded in 1967, Executive Order 11246, which required federal contractors to “take affirmative action” to ensure that people are hired and treated during employment without regard to their race, color, religion, sex, or national origin. By 1972 this presidential mandate, together with the legal ban on discrimination, led to federal pressure on employers (and then schools and housing providers) to take positive steps to correct past wrongs by giving “preferential treatment” to minorities and women. Before long, quotas were introduced, setting “goals” for protected classes of Americans and “timetables” for achieving them. White males responded with cries of “reverse discrimination”: Complaints before the Equal Employment Opportunity Commission, state human rights agencies, and federal and state courts numbered in the hundreds of thousands. A few cases reached the Supreme Court.

In a series of split and often very close decisions on both sides of the affirmative action debate, the Supreme Court itself added to the controversy. In Regents of the University of California v. Bakke in 1978, the Court in a five-to-four decision prohibited a California medical school from using a quota—reserving a specific number of places—for minorities in admissions. A year later, however, in United Steelworkers of America v. Weber, the same court ruled that it was okay for the steelworkers union to select only minorities for a special training program. Two cases two years apart, both involving firefighters, are also contradictory. In 1984, in Firefighters Local Union No. 1784 v. Stotts, it was decided that seniority was more important than race, that the City of Memphis could lay off recently hired minorities first in staff reductions. However, in International Association of Firefighters v. City of Cleveland (1986), the municipality was permitted to promote minorities over more senior whites. Three recent cases, two concerning the same educational institution, have further confused the issue of affirmative action with decisions that alternately sustained and reversed earlier rulings. In Texas v. Hopwood (1996) the high court let stand a lower court decision that race could not be used in college admissions. In Gratz v. Bollinger (2003), in a six-to-three decision the University of Michigan’s strict formula awarding advantage based on race for admissions was struck down, but in the very same year, in Grutter v. Bollinger, by five to four the University of Michigan Law School was permitted to use race as a factor in admissions.

**FUNDING PROBLEMS**

Funding the Great Society initiatives became difficult beginning in 1968 because of the burden of the Vietnam War, Johnson’s reluctance to ask Congress for a tax increase, and the goal of reaching a balanced budget. Many of the programs had no political constituencies, that is, they did not originate from outside lobbying and thus lacked the support necessary for continued financing. Johnson’s decision to withdraw from the 1968 presidential race further weakened his advocacy of government intervention on the side of racial justice and economic equality. Under the Republican administration of President Richard M. Nixon, in 1969 the OEO was dismantled and its poverty programs transferred to other federal agencies. Democrat Jimmy Carter’s one-term presidency, bogged down with the twin problems of inflation and recession, did little to restore the earlier funding for social causes. Carter offered no new initiatives along the lines of Johnson’s program, focusing instead on international affairs.

In the 1980s Ronald Reagan’s strong conservative views on the role of government and federal spending, combined with a Republican Congress’s disinclination to continue social programs, led to draconian cuts for the Great Society. The huge increase in appropriations for the military during this period further tolled the bell for the two-decades-old set of domestic programs. The administration of George H. W. Bush (1989–1993) essentially held fast to the new conservative agenda in Washington. By the time Bill Clinton took the oath of office in 1993 the Democrats had accepted the hard fact that most of the Great Society goals had not been, nor could they ever be, accomplished, and they did not push for new social legislation. Clinton’s failure to get approval for a national health insurance program but success at passing a welfare reform bill only served to scale back the accomplishments of earlier Democratic presidents. Welfare reform now meant that time limits were imposed on the benefits received, able-bodied adult recipients were required to perform public service work, and more rigorous eligibility requirements were imposed, changes all contrary to Johnson’s original goals for a better America. Under the administration of George W. Bush, which began in 2001, the Republican Congress did not kill all previous social programs, and it kept up some funding, but Bush’s efforts toward the global war on terror and his initiation of the war in Iraq devoured budget surpluses and rendered impossible any meaningful attempt to reinvigorate Great Society spending, just as the war in Southeast Asia had almost four decades earlier.
THE GREAT SOCIETY REVISITED

The Great Society has always been closely identified with Democratic political agendas and the cold war liberalism of the 1960s. It was premised on Johnson’s “guns and butter” approach, the idea that the United States can wage wars against communism in far-off places and, at the same time, still provide sufficient funding for domestic social programs. Critics of the Great Society were from the start skeptical of the federal government’s ability to bring about the promised social change, and they are credited with paving the way for the conservative backlash of later decades. In the post-Vietnam era, liberal thinking gave way as Americans lost confidence in the effectiveness of military interventions. The cold war liberal Democratic presidents (Truman, Kennedy, Johnson) freely used military might to solve international problems (as in Korea, Cuba, the Dominican Republic, and Vietnam), but later Democratic presidents (Carter, Clinton) were reluctant to use force and turned to diplomacy instead (as in Panama, the Middle East, and the Balkans).

The War on Poverty, perhaps the most ambitious feature of the Kennedy-Johnson proposals, was also the most controversial and it has left a mixed legacy. Billions were spent on dozens of programs, but the poverty rate was just modestly reduced in the late 1960s, only to rise again in the 1970s and 1980s due to changing economic and social conditions. The leftist critique of the Great Society claimed that throwing money at problems will not solve underlying social problems without fundamental changes in the structure of the economy and the reduction of inequality in America. Nevertheless, Johnson’s “other war” permanently expanded the U.S. welfare system, gave the federal government important new responsibilities, and provided a “safety net” of programs and benefits that poor people rely on today.

Despite reductions in programs and funding, much of what comprised the Great Society has aided the middle class, not just the poor, and is still with us in some form. Medicare and Medicaid, frequently criticized as wasteful and inefficient, have grown considerably and now enjoy wide political backing. Despite welfare reform, with its “workfare” provisions, the poor have not been thrown out on the street, and public assistance to the non-poor has actually increased. Federal funds for public and higher education are appreciably greater since the Great Society days, probably because they have been supported by both Democrats and Republicans over the years. Importantly, funding for transportation and the environment has continued, and funds earmarked for the arts, humanities, and public broadcasting have survived in the face of many attempts to eliminate them.

All of the civil rights laws, amended many times and continually challenged in the courts, remain on the books, but the Supreme Court, much altered with conservative justices appointed by Republican administrations, has weakened attempts at affirmative action in education, housing, and the workplace. In the face of the recent Gratz and Grutter decisions, the reconstituted court may now have an anti-affirmative action majority. The 2004 election, however, may have demonstrated that cold war liberalism is not dead. Senator John Edwards, campaigning for the Democratic nomination on a platform of old Great Society ideas and promises, did well in the primaries. The selection of Edwards as the running mate of John Kerry, a more moderate politician and well-known early critic of the Vietnam War, was perhaps a final accession to Johnson’s outmoded programs.

Well into the first decade of the twenty-first century, it is apparent that the ideals first proposed by President Kennedy, expanded by President Johnson, and enacted into law by a Congress bent on building a better America, are not forgotten. Perhaps Edward M. Kennedy, in his 1980 speech before the Democratic National Convention, summed it up best. He had just pulled out of the race for his party’s nomination, ostensibly ruling out any further attempt to reclaim his martyred brother’s presidency. The senator from Massachusetts, in a patent reference to the liberalism of the New Frontier, poignantly expressed the sense of the Great Society for future generations when he exclaimed: “… the work goes on, the cause endures, the hope still lives, and the dream shall never die.”

GREAT TULIP MANIA,
THE
The Great Tulip Mania refers to the spectacular rise and fall in the price of tulip bulbs between the end of 1634 and February of 1637 in what is now the Netherlands. The episode is less significant as an event of great historical importance than as a paradigm of a speculative mania ending in a panic, and it produced a term, tulipomania, that often is used as a metaphor for economic bubbles.

References to the Tulip Mania in economics and finance cite Charles MacKay’s 1852 account, though, as with the event itself, the value of this account lies more in its portrayal of the emotions and irrational action that typify frenzied speculation than in its veracity as historical record. Such references typically motivate discussions of the dynamic instability in heterogeneous capital goods models and discussions of speculative bubbles in financial markets.

Nicholaas Posthumus (1929) provided English-language readers with the first serious documentation of historical details and an interpretation of the event based on excerpts from contemporaneous pamphlets and notary transcripts. Centered in the tulip-growing region of the municipality of Haarlem, the mania was the result of a speculation in tulips that spread from professional tulip growers and experts to those who had no previous connection to bulb growing, first the wealthy and then the lower-middle and working classes.

As much as historians are able to discern from surviving records, evidence suggests that there was heightened speculation in the trading of contracts on rare, and later common, tulip bulbs. At its peak, the event saw the rarer bulbs commanding prices that exceeded the estimated average annual per capita income by a considerable margin. Yet, whether the prices were “excessive” in relation to the fundamental, nonspeculative elements governing the demand for and supply of the bulbs is as debatable as the possibility that the subsequent crash in the market for tulip bulbs caused any economic crisis. What is apparent is that institutionally, the episode is an early experience with futures and options contracts, although this emerged only after the fact when a group of professional traders, attempting to calm the market, permitted holders of futures contracts the right to decline to buy in exchange for a small fraction of the previously agreed-upon price.

Researchers have examined the records of the seventeenth-century tulip market for evidence of a speculative bubble with prices rising in excess of that which might have been warranted by fundamentals. Peter Garber’s 1989 study, for example, suggests that the bulb speculation did not lead to obvious excesses, at least for much of the 1634 to 1637 “mania.” As with most attempts to debate the efficiency of a given market wherein prices reflect fundamentals rather than irrational speculative influences, conflicting interpretations typically revolve around the interpretation of econometric signals. There will always exist scope for considerable debate, however, because a speculative bubble in the market price of tulips—or any other object of speculation—is indistinguishable in the data from time-varying expected returns and disappointed but otherwise well-grounded expectations of optimistic outcomes.

GREEK ORTHODOX CHURCH
The Greek Orthodox Church refers to any number of Eastern Orthodox Church groups whose heritage derives predominantly from Greek language and culture. These churches are organized around three Greek-speaking patriarchs (exalted bishops who historically have co-administered the Orthodox churches): the Ecumenical Patriarch, who resides in Constantinople (Istanbul) and has jurisdiction over present-day Turkey and all Christian

Raymond M. Weinstein
areas beyond those territories that have been explicitly designated to another jurisdiction; the Patriarch of Jerusalem who presides primarily over Palestine; and the Greek Patriarch of Alexandria, who is responsible for Egypt and all of Africa. For historical reasons, three separate relational patterns have emerged between these Greek Patriarchs and their daughter churches:

1. **Eparchy**: Some Greek Orthodox Churches are Patriarchal eparchies, ecclesiastical provinces that are directly under the auspices of one of the three Greek-speaking Patriarchs. These include the large emigrant churches formed in the West such as the Greek Orthodox Archdiocese of North and South America (formed in 1922, with about 1.5 million members) and the Greek Orthodox Archdiocese of Australia (formed in 1924, with about 400,000 members). The leaders of these churches are usually given the title Eparch, Metropolitan, or Archbishop and are selected by the Holy Synod of the Ecumenical Patriarch with advice of a local synod of bishops.

2. **Autonomous**: Autonomous churches operate with full administrative independence but have leaders who are chosen or affirmed by a Patriarch. Autonomous Greek Orthodox Churches include the small but important Church of Sinai, which is limited to the famous Monastery of Saint Catherine and several dependencies.

3. **Autocephaly**: As self-governing churches, autocephalous churches have hierarchies independent of the Patriarch and operate with complete independence. While maintaining ecclesiastical and theological communion with the Patriarchs, these autocephalous Greek Orthodox Churches are responsible for all church matters affecting the life and administration of the church with the exception of doctrinal and canonical positions. Historically, these churches often emerged as a result of nationalistic movements and are closely identified with the national ethos of the people. The largest Greek Orthodox autocephalous churches are the Church of Greece (formed in 1833, with about 8 million members) and the ancient Church of Cyprus (formed in 431, with about 1 million members).

All of the Greek Orthodox Churches trace their origins to the earliest Christian movements, which were primarily composed of Greek-speaking Christians in the Eastern Roman Empire. While Rome remained an important religious center from Christianity’s inception, most of the growth and theological development during the first four centuries of Christianity occurred in the Greek-speaking East. The unity of the Eastern Christians was repeatedly challenged, leading to a major schism in 451 that resulted in the formation of a Coptic Christian Church in Egypt. Because of cultural, political, and theological differences, a gradual estrangement emerged between the remaining Greek-speaking Christians of the East and the predominantly Latin-speaking Christians of the West. This led to the “Great Schism” of 1054, which became entrenched after the Fourth Crusade, during which western Christians sacked the eastern capital of Constantinople. After the fall of Constantinople to Islamic forces in 1453, the theological and liturgical center of Eastern Christianity shifted to Russia until the twentieth century. The Greek churches continue to be out of communion with the Roman Catholic Church, despite repeated attempts for reunification.

Greek Orthodoxy stresses two foundations for the church’s beliefs: the Bible, which is believed to be inspired by God, and Holy Traditions that have been passed down through the church. The primary dogmas of the church, including the nature of the Trinity, the person of Jesus, the role of the Virgin Mary, and the veneration of icons, were defined in seven “Ecumenical” councils that the Greek churches share with the Roman Catholic Church. Compared to Western theology, Greek Orthodoxy tends to emphasize a direct mystical encounter with God gained through ascetic and liturgical practices rather than emphasizing discursive reasoning as in the West. The ultimate goal is described as deification of the human person through sanctification by Christ. The sacraments, called mysteries in the East, are seen as transformative vehicles that guide the human person toward deification.

Greek churches are led by celibate bishops who stand in apostolic succession to the original apostles. Local churches are led by priests and deacons who are usually married and always men. Historically, there was no official number of sacraments, though baptism and the Eucharist service are universally recognized as the central pillars of the Greek Christian life. One of the most distinctive aspects of Greek Orthodox worship is the use of icons—paintings of saints, the Virgin Mary, and Jesus—that are seen as “windows into heaven.” The most important holiday is Easter, called Pascha (Passover) in Greek churches, which is understood as Jesus’ resurrection destroying “death by death,” thus offering everlasting life to those who believe.

**GREEN BOOK, THE**

*(LIBYA)*

The driving force behind *The Green Book* was Qadhafi’s resolve to consolidate and formalize the revolution set in motion by his ascent to power in 1969. By the time it attained independence on December 24, 1951, Libya was a poor and underdeveloped country. The discovery of oil in 1955 generated significant wealth but no corresponding benefits to the impoverished majority of Libyans because the monarchical government’s unchecked corruption, fiscal malfeasance, and nepotistic inclinations encouraged brazen exploitation by some Western powers and their proxies. It was against this backdrop of corrupt administration and international exploitation and popular disillusionment and discontent that Qadhafi emerged.

Armed with a vision to unify the Arab world (in the mold of his hero, Egypt’s Abdel Gamal Nasser) and the grudges of anticolonialism, Qadhafi led a small group of his fellow military officers known as the Unionist Free Officers and toppled King Idris in a bloodless coup on September 1, 1969, marking the end of the monarchy.

On his ascent to power, Qadhafi embarked on changing Libya from a conservative postcolonial state to a modern progressive one. He launched a “cultural revolution” in 1973 to inspire a major transformation of society through changes in roles, attitudes, perceptions, and behaviors. In *The Green Book* he explicated the philosophy of the revolution as a national guide to the complete eradication of the old order and its replacement with a new order governed by the ideals of liberty, unity, and socialism.

The main thrust of Qadhafi’s philosophy is the removal of all vestiges of foreign influence and ideologies and the establishment of a new society based on the basic principles of Islam and homegrown socialism. He condemns parliamentary democracies and their components in preference to socialism and progressive Islam, rejects capitalism and communism as false ideologies, and develops his “third universal theory” in which he envisions the dismantling of the traditional apparatus of government and the establishment of a form of direct democracy through institutionalized use of popular congresses and committees at the local, regional, and national levels to guarantee mass participation in the nation’s decision-making process. This form of government has been in place since March 2, 1977, when Qadhafi declared Libya a *jamahiriya* (government of the masses), although critics see a stiflingly rigid structure that provides no mechanism for a democratic change of government. At any rate, Qadhafi believes that adherence to the basic fundamentals of Islam in line with the third universal theory will enable Libyans to lead Muslims everywhere toward economic development and political change. However, Qadhafi’s unorthodox approach to Islam and his elevation of *The Green Book* as a guide to the emancipation of the human race has brought him into conflict with Muslims in Libya and beyond. Although *The Green Book* professes universality in its scope and purpose, the peculiar circumstances of the Libyan people and the Islamic Arab heritage underlie its general framework.

**GREEN REVOLUTION**

*Green Revolution* is the term applied to the introduction of “modern” crop varieties in developing countries beginning in 1964–1965. The Green Revolution was introduced at different rates in different countries. It was produced by more than five hundred National Agricultural Research Systems (NARS) in developing countries and supported by eight International Agricultural Research Centers (IARCs) located in developing countries. IARCs produced roughly 35 percent of Green Revolution Modern Varieties (GRMVs), which included highly productive lines of rice and wheat. NARS produced 60 percent of...
GRMVs. Private sector breeders in developing countries produced 5 percent of GRMVs. Developed countries did not produce GRMVs for developing countries.

Twelve countries with populations in 2000 of one million or more did not have a significant Green Revolution (these countries had less than 2 percent GRMV adoption in 2000). Nine of these countries were in sub-Saharan Africa. An additional eighteen countries had less than 10 percent GRMV adoption in 2000 (eleven of these were also in sub-Saharan Africa). Another eighteen countries had less than 20 percent GRMV adoption in 2000 (twelve of these were in sub-Saharan Africa). Forty-five countries had significant Green Revolutions.

The forty-eight countries with low levels of GRMV adoption had low levels of crop value per hectare because crop yields were low. They used very little fertilizer and had low rates of productivity growth. The UNIDO index of industrial competitiveness for these forty-eight countries was low. Most of these countries were small. By contrast, the countries with significant Green Revolutions were larger countries (including India and China).

In 1960 birth rates were similar for all developing countries. By 2000, birth rates in the successful Green Revolution countries had declined to roughly half of the birth rates of 1960. For the unsuccessful countries, birth rates declined by only 15 percent. Food consumption per capita (as measured by calories consumed per capita) increased by 10 percent for the unsuccessful Green Revolution countries and by 25 percent for the successful Green Revolution countries. The unsuccessful countries increased food consumption because the “real” prices of food grains in world markets declined. In 2000 the real prices of food grains in world markets were 40 percent of their 1960 levels. Child mortality rates improved for all countries because of better diets.

The Green Revolution was criticized by two groups. In the 1980s it was criticized because farmers adopting GRMVs used more fertilizer. The first two GRMV crops were wheat and rice, and indeed fertilizer use did increase for these crops. It was also widely perceived in the 1980s that GRMVs were adopted only in “favorable” production environments. The second round of critics, who appeared at the end of the 1980s, emphasized environmental factors and increased use of chemicals.

The Green Revolution is continuing as new generations of GRMVs are being developed, and overall GRMV production is increasing, not declining. For example, by the 1990s two IARCs, ICRISAT in India and ICARDA in Syria, had begun developing GRMVs for unfavorable semi-arid and dryland conditions. The Green Revolution is seen today as having had a major impact in spite of its “uneven” delivery.

GREENHOUSE EFFECTS

The natural greenhouse effect was first described by Joseph Fourier (1768–1830) in 1827. Solar energy reaches the earth in the entire spectrum. The earth reemits this energy as infrared radiation. Greenhouse gases in the atmosphere, such as water vapor and carbon dioxide, absorb outgoing infrared radiation and reemit it in any direction. As a result the earth holds more energy than it would have without the presence of greenhouse gases. The natural greenhouse effect raises the global annual surface air temperature by some 90 degrees Fahrenheit (30 degrees Celsius) and therefore enables life as we know it.

The enhanced or anthropogenic greenhouse effect was first described by Svante August Arrhenius (1859–1927) in 1896. Deforestation and coal burning release carbon dioxide, which accumulates in the atmosphere. As a result the greenhouse effect is strengthened, and temperatures rise.

The enhanced greenhouse effect was long a curiosity in the natural sciences. In the 1970s the first climatologists were more worried about global cooling—as the next ice age was overdue and temperatures were falling, probably because of sulphur emissions (now reduced because of concerns over acid rain). Global warming returned to the scientific agenda in the early 1980s and got on the political agenda a decade later.

The enhanced greenhouse effect is clouded by large uncertainties caused by imperfect data, limited computing power, and the vast complexity of the earth system. There is virtual agreement, however, that temperatures will rise, and more so at the poles, during winter and at night. Rainfall patterns will change and may well intensify—leading to droughts in some places and in some seasons.
and floods in others. Storms may become more frequent and intense, but the evidence for this is weak where this matters most, namely in the tropics. Rising temperatures will cause sea levels to rise, mostly through expansion of seawater but perhaps also through ice melt.

The uncertainty about how the climate would respond to greenhouse gas concentrations is compounded by the uncertainty about future emissions, which depend on the number of people, their economic activities, and the types of energy they will use. High future emissions would put the earth into a state it has not been in for millions of years, perhaps with strongly nonlinear consequences.

Impacts of climate change are many. Less heating would be needed in winter, but more cooling would be needed in summer. Heat-related diseases would increase, but cold-related ones would decrease. Tropical diseases may spread or intensify. Lands would drown unless costly dikes are built. Crops would benefit from the higher carbon dioxide concentration but may be hurt by drought. Tourists would seek different holiday destinations. Urban infrastructure, particularly for water discharge, would need to be redesigned. Vegetation patterns would change, probably at the expense of many specialized plants and animals. Aggregate estimates suggest that the initial warming may be positive but that greater warming would bring net damages. Poorer countries would suffer greater damages.

Carbon dioxide is the main anthropogenic greenhouse gas, followed by methane and nitrous oxide. Carbon dioxide is emitted by the burning of fossil fuels and by deforestation. Methane comes from agriculture, waste, and fossil fuel production; nitrous oxide comes from agriculture and industry. Chlorofluorocarbons (CFCs) are greenhouse gases too, but they have been phased out to protect the ozone layer. Their replacements, hydrofluorocarbons (HFCs), are even stronger greenhouse gases.

Greenhouse gases can be reduced by slowing or even reversing economic growth. This was shown to be particularly effective when the Soviet Union collapsed, but it is also responsible for the limited emissions growth in western Europe and Japan. Alternatively energy efficiency can be improved, alternative fuels can be used, or emissions can be captured and stored (biologically or geologically). Substantial emission reduction can be achieved with proven technologies. The costs would be small if policies are implemented gradually and implementation allows for flexibility.

Because greenhouse gases stay in the atmosphere for decades and longer, it does not matter where they are emitted. International coordination is needed for an effective solution. The oceans respond only slowly to changes in greenhouse gas concentrations. Energy infrastructure lasts for decades. As a result both the climate change problem and its solutions span many electoral cycles. Climate policy is therefore weak. The United Nations Framework on Climate Change is universally accepted, but it establishes obligations only to report emissions and to negotiate. Its first implementation, the Kyoto Protocol, sets targets for a limited number of countries only; of these, some have abandoned the treaty, while others are likely to meet their targets by coincidence rather than design.

Climate change has become a cultural phenomenon too. The press and television devote considerable attention to climate science and policy. Major motion pictures are devoted to the topic, and climate change regularly features in advertisements for a wide range of products, sometimes without an obvious connection.

GREENSPAN, ALAN

1926–

Alan Greenspan spent much of his career at the highest levels of government economics. He served as a top advisor to presidents Ford and Nixon, but is most widely known for his long tenure as chairman of the Federal Reserve, a position he held from 1987 to 2006.

For much of that period, Greenspan was arguably the most influential economist in the world. His early reputation as chairman of the Fed was boosted by his able handling of the 1987 stock market crash, wherein he quickly provided the economy with the liquidity needed to offset the market’s falloff. Beginning in the mid-1990s, Greenspan was among the first to recognize the importance of productivity’s acceleration. Given this increase in the growth of output per hour, Greenspan believed that the economy’s “speed limit”—the rate of growth consistent with stable inflation—had increased. During the latter 1990s, the unemployment rate fell well below the comfort level of most economists, yet inflation decelerated, and broadly shared real wage gains were handily paid for out of rising productivity growth.
Greenspan was widely viewed as favoring conservative economic policy, a view reinforced by his early association with the libertarian, antiregulatory philosophy of the writer Ayn Rand. And while he exhibited throughout his career a strong preference for market-driven outcomes and a diminished role for government, his approach to monetary policy was largely pragmatic and data-driven. Though he avoided true “inflation-targeting”—explicitly stating the range of price growth acceptable to the Fed, a practice he viewed as too restrictive—he focused closely on measures of inflation and resource utilization, urging the Federal Open Market Committee (the group of Fed governors that set interest-rate policy) to adjust rates based on the relationships between these variables.

Though generally highly regarded by the economics and policy community, Greenspan has had his critics. Throughout his term at the Fed, he was sometimes viewed as elevating inflationary concerns above the goal of full employment, despite the Fed’s mandate to maintain balance in its simultaneous pursuit of stable prices and low unemployment. Most recently, some have maintained that Greenspan played a decisive role in the swing from fiscal surplus to fiscal deficits. Based on what turned out to be a highly optimistic forecast of government revenues, Greenspan endorsed large tax cuts proposed by the Bush administration. Though the chairperson of the Fed is a political appointee, it is rare for the Fed chief to play such an overtly political role in a policy matter before the Congress. Furthermore, his endorsement was instrumental in the passage of these cuts, which ultimately played an integral role in the move from federal budget surpluses in the latter 1990s to deficits in the 2000s.

The most common criticism of Greenspan, however, is that he presided over damaging investment bubbles that could have been avoided by more aggressive Fed policy. Two major speculative bubbles emerged over Greenspan’s tenure: the information technology (IT) bubble of the latter 1990s and the housing bubble of the 2000s. Speculation in IT firms, some of which had little more than a sketchy business plan, was rampant in the 1990s, while at the same time, many firms overinvested in IT-related goods and personnel. When it became clear that returns on these investments could not be sustained, a large sell-off of stocks and IT-related assets ensued. Shortly thereafter—in March 2001—the economy entered an investment-driven recession.

More recently, speculative bubbles formed in housing markets as prices were steeply bid up, particularly in highly populated areas of the country. Though Greenspan observed the sharp rise in home values, he again refrained from criticizing the development of what some observers recognized as a housing bubble. In fact, critics argue that Greenspan and the Fed further inflated the bubble by sharply lowering interest rates in response to the recession of 2001. Moreover, many homeowners took advantage of the rising value of their home equity, and boosted their consumption with cash borrowed against their homes. As this bubble began to burst in the mid-2000s, home prices fell steeply, slowing the economy and hurting key economic sectors, such as construction and real estate.

In both cases, Greenspan and the Fed did nothing to intervene as speculative bubbles formed. During the formation of the IT-bubble in 1996, Greenspan popularized the oft-repeated term “irrational exuberance,” suggesting speculation was inflating asset values. Thereafter, however, he refrained from either critical scrutiny of the stock market’s run-up, or more concrete policies, such as raising the Fed’s margin requirements (i.e., limiting the amount that investors could borrow to purchase stocks “on margin”).

Prior to retiring from the Fed, Greenspan defended his lack of action in these cases by claiming the Fed has neither the ability to recognize bubbles, nor the tools to deflate them. Especially given the fact that Greenspan himself clearly recognized the irrational nature of the stock market’s climb in the latter 1990s, the first part of this defense seems weak. Whether the Fed could have intervened is another question. Reflecting on the IT bubble, Greenspan reasonably argued that “it was far from obvious [that the bubble] could be pre-empted short of the central bank inducing a substantial contraction in economic activity, the very outcome we were seeking to avoid” (Greenspan 2002).

These criticisms aside, Greenspan will likely be remembered in a positive light, as an excellent crisis manager and an able central banker who presided over two of the longest economic expansions in the country’s history. True, his conservative political ideology inappropriately broke through on occasion, and he might have led the Fed to do more to push back against speculative bubbles that formed on his watch. Nonetheless, his economic insights and data-driven approach to monetary policy remain the model for central bankers today. In fact, when nominated by President George W. Bush to succeed Greenspan, current Fed chief Ben Bernanke paid a high compliment to the retiring chairman: “[If] I am confirmed to this position, my first priority will be to maintain continuity with the policies and policy strategies established during the Greenspan years” (The White House 2005).

GRENADIAN REVOLUTION

Residents on the 121-square-mile tri-island nation of Grenada, Carriacou, and Petit Martinique (population 110,000) awoke on the morning of March 13, 1979, to radio reports that the elected government of Prime Minister Eric Gairy had been replaced in a relatively bloodless coup by the New Jewel Movement (NJM). The NJM set up the People’s Revolutionary Government (PRG) with the avowed task of transforming Grenada’s society and political culture and creating a socialist state.

REVOLUTIONARY ORIGINS

Seeds of this revolution had been sown during the previous twelve years of Gairy’s rule, during which he had alienated many Grenadians through his increasing use of legal and extralegal means to silence his critics. Chief among these techniques was his seizure of the lands and property of his political opponents, intimidation of civil servants, the establishment of a system in which decision-making depended on the Gairy-dominated Cabinet, and the establishment of an extralegal paramilitary body that inflicted bloody beatings on his political opponents.

The emergence and rise of the NJM must be seen within the context of several international movements of the late 1950s and 1960s that had a great impact on the Caribbean. The Cuban Revolution, successful independence struggles in Africa, the growth of Rastafarianism, and the U.S. civil rights movement were all inspirational in the English-speaking Caribbean. By the 1970s, the flourishing of new ideas shaped by these international developments had produced a generation of young people who openly questioned the appropriateness of the inherited British political system. Guyanese-born university lecturer Walter Rodney had also shown the relevance of Black Power to the cultural and political situation in the Caribbean.

In Grenada, Maurice Bishop was among this new generation of Caribbean activists. On returning home from England, where he had studied law and had been politically active, Bishop teamed up with another London-trained lawyer, Kendrick Radix, to form an urban-based study group, the Movement for the Assemblies of the People (MAP). At the same time, Unison Whiteman founded another group to promote rural development, the Joint Endeavour for Welfare, Education, and Liberation (JEWEL). In March 1973 these groups merged into the NJM, which advocated agricultural and educational reform, preventive medicine campaigns, social planning, the nationalization of banks, the phasing out of foreign-owned insurance companies, an end to party politics, and the institution of People’s Assemblies as the mechanism to ensure participatory democracy and the permanent involvement of the working people in decision-making. Their model was Tanzania’s Ujaama system.

The NJM flourished during a period of pervasive clientelism, political conservatism, and corruption on the part of Grenada’s two main political parties. As its influence grew and the number of its sympathizers and followers increased, the NJM was increasingly attacked by Gairy who sought to silence its supporters. As the NJM made increasing inroads into the trade union leadership, Gairy passed laws in early 1978 prohibiting strikes and introducing compulsory arbitration to settle disputes where “essential” services were affected.

Partly because of the terror he had unleashed on his political opponents, particularly NJM members, Gairy’s political base was being systematically eroded. A history of dubious electoral practices, including alleged use of rigged electoral lists, caused the NJM to despair of effecting governmental change at the polls despite the fact that by 1978 some of their members had won election to the legislature. By then, most Grenadians were apparently fed up with Gairy’s misrule. Thus, when the NJM seized power in 1979, few Grenadians complained.

THE REVOLUTIONARY MOVEMENT

Once in office, the PRG consolidated its power by forming a government that included members of the mercan-
tile community and persons of middle class background. This temporarily allayed the fears of individuals concerned that the country would soon be turned into a Cuban-style socialist state. Though they suspended the 1974 constitution, the PRG retained the office of governor general in an obvious attempt to gain the support of the politically conservative Grenadian and British Caribbean peoples. As prime minister, Bishop signed into effect laws that were passed by the Parliament, of which he was a part, in the name of the PRG.

While pledging to observe fundamental rights and freedoms of Grenadians, the PRG also declared its determination to eradicate all vestiges of Gairyism and to protect the revolution. It established a People’s Revolutionary Army (PRA), whose members had the same powers of arrest and search that members of the local police force enjoyed. By using preventive detention without bail, the PRG could detain indefinitely persons suspected of activities aimed at undermining the revolution or deemed prejudicial to public safety or public order. This proved to be a sore point for Grenadians who had expected the PRG to respect their human and civil rights. Although the government had pledged a Consultative Assembly where Grenadians would participate in shaping a new constitution, by 1980 PRG members were openly asserting that elections and a return to parliamentary government were no longer priorities.

The revolution did have positive effects on Grenada, however. The awakening of national spirit on an unprecedented level was evident in the widespread use of voluntary labor for community development. Educational and medical improvements stemmed from the generous assistance provided by Cuban doctors and teachers. Farmer cooperatives expanded agricultural output. Marketing boards regularized the availability of these goods locally and in neighboring Caribbean countries. Agribusiness initiatives transformed surplus fruits into canned nectars and juices. A spice-grinding project brought to the marketplace a range of locally produced and packaged spices. The Livestock Production and Genetic Centre set place a range of locally produced and ground packaged juices. A spice-grinding project brought to the market.

Providing technical expertise, heavy equipment, and skilled labor for the construction of the airport. Syria, Libya, Iraq, and Algeria provided more than US$19 million, while Venezuela donated much-needed diesel fuel.

This reliance on aid from leftist countries irked the United States, which, increasingly concerned about the leftward drift of the revolution, feared that Grenada would become a proxy for the Soviets. President Ronald Reagan openly declared that the new airport was for military rather than economic purposes. PRG fears that the United States would destabilize its experiment in socialism forced the revolutionaries to boost the country’s military preparedness through a series of secret agreements with Eastern European countries. According to these agreements, Grenada would receive counterintelligence equipment, agent training, and arms and other military materiel. Local preparedness was enhanced through participation in the army, militia, and other neighborhood bodies geared to protecting the revolution at home.

The greatest threat to the revolution eventually came not from the United States or local counterrevolutionaries, but from the revolutionaries’ own actions. Long-suspected though rarely publicly articulated ideological differences within the NJM leadership came to light in October 1983. Minutes from Central Committee meetings reflect a sharp divide centering on leadership issues and the direction the revolution should follow. It appears that revolutionary élan was receding partly because the revolutionaries had allowed their rhetoric to exceed the possibilities the situation allowed. An awareness of the revolution’s failure to achieve its full potential led to serious self-reflection and evaluation of both the leadership and the governmental structure. In addition, personal differences contributed mightily to the internal crisis that the PRG experienced in the autumn of 1983. Bishop’s detractors accused him of being inefficient and middle class, and of lacking political leadership skills and sufficient ideological coherence. After much debate over three days, the party proposed the institution of a joint leadership structure, with power to be shared by Bishop and Bernard Coard. Bishop initially accepted this proposal. Two days later, he left for a visit to Hungary and Czechoslovakia.

On his return via Cuba on October 8, Bishop told Central Committee members that he was no longer willing to go along with the power-sharing proposal the party had approved. Committee members then sought to impose this agreement without the support of Bishop. In response, Bishop, who was for many the personification of the revolution, set out to turn the people against Coard by spreading a rumor that Coard was conspiring to kill him. Confronted at a Central Committee meeting with his security guard’s testimony about this plot, Bishop
remained silent. Convinced of his guilt, the Central Committee placed him under house arrest.

Bishop’s house arrest failed to neutralize him; instead, it roused the people. After days of unrest, Unison Whiteman and George Louison, two of Bishop’s faithful supporters, began organizing protestors for a rescue attempt. By this time, all the ministers, except Bishop, Selwyn Strachan, and Hudson Austin, had resigned their portfolio. Government was in disarray. On October 19, 1983, Whiteman and a group of Bishop loyalists freed Bishop. Bishop then led a crowd to Fort Rupert, the headquarters of the Grenadian armed forces, with the apparent goal of using the military to reassert his authority. Accounts of what transpired there differ. Speaking for the PRA, General Hudson Austin later claimed that Bishop’s group disarmed the soldiers guarding the fort and declared their intention to eliminate the entire Central Committee—the senior members of the party—and to smash the revolutionary armed forces. Thus, Austin declared, relief soldiers were sent to reestablish control of Fort Rupert. Bishop and his group fired on the soldiers, prompting them to retaliate. In the crossfire, Bishop, a number of his colleagues, and an unknown number of citizens were killed in what many regard as an execution. The bodies of Bishop and the ministers were reportedly burned beyond recognition and then secretly buried. Some suggest that U.S. forces removed the charred remains from the island.

The killing of these ministers created a leadership vacuum that the PRA under Austin initially sought to fill. Because the army lacked popular support, it declared a twenty-four-hour curfew to both maintain order and impose its will on the people. Fearful of governance by the group that had killed their popular prime minister, Grenadians panicked. At the request of Governor General Sir Paul Scoon, who invoked the doctrine of necessity embodied in the 1974 constitution and assumed plenipotentiary powers, forces from the United States and the Caribbean staged a military intervention that quickly eliminated remaining pockets of resistance from the PRA and Cuban sympathizers. Grenadians viewed the foreign troops as liberators rather than as invaders.

In an attempt to restore a state of political normalcy, Sir Paul appointed a broad-based advisory council to form an interim government that would help in the country’s administration. Among its most memorable achievements was paving the way for the elections that took place in December 1984.

By then, Coard and those suspected of involvement in the killings at Fort Rupert had been detained. They were tried and found guilty of murder, but their death sentences were later commuted to life imprisonment by the governor general. A successful appeal to the Privy Council resulted in a 2007 ruling that they should be resentenced because of the unconstitutionality of the original sentences.

GROSS DOMESTIC PRODUCT

As a measure of the aggregate level of economic activity, gross domestic product (GDP) is the main indicator used to monitor the state of an economy. GDP growth, commonly referred to as economic growth, is thus of great interest to policymakers for the conduct of fiscal and monetary policy. It is also widely used to measure productivity of an economy.

GDP is defined as the value-added of all goods and services produced in a given period of time within a country. The measurement of GDP can be approached from three angles: value added by industry, final expenditures, and factor incomes.
- Value added created by industry (output less inputs purchased from other producers);
- Expenditures by consumers, businesses on investment goods, government on goods and services, and foreigners for exports (minus expenditures by domestic residents on imports); and
- Incomes generated in production, operating surplus generated by business and compensation of employees.

GDP is usually expressed in terms of current prices in national currency units, or in real terms (real GDP) after removing the effects of price change to reflect the volume of production in the economy. For international comparisons, GDP is also expressed in a common currency such as U.S. dollars using purchasing power parity exchange rates.

Up to the 1980s, the term gross national product (GNP) was more commonly used than GDP. The former, more correctly called gross national income (GNI), includes incomes of residents of a country earned abroad and excludes incomes from domestic production sent abroad. In contrast, GDP includes only domestically produced incomes. GNI in combination with GDP are often expressed in per capita terms and used as measures of living standards of the nation.

National income accounting (the methodologies to measure GNI and GDP) originated in the 1930s and 1940s with the work of Simon Kuznets in the United States and Richard Stone in the United Kingdom. A detailed history of national accounting is found in Andre Vanoli’s work *A History of National Accounting* (2005). Since the 1950s, the United Nations, working with other international organizations such as the International Monetary Fund, World Bank, and Organization for Economic Cooperation and Development, has coordinated the development of international standards for the national accounts. The current international standard was last issued in 1993. These standards evolve over time with the world economies, and a new edition of the standard will be released in 2008. The International Association for Research in Income and Wealth was founded in 1947 for the advancement of knowledge related to national accounting. The publications of this Association, including the journal *Review of Income and Wealth*, document the evolution of the field.

GDP is not a measure of economic welfare. It does not incorporate into its official estimates environmental degradation and resources depletion, nor the value of leisure. Neither does it take into account the influence on income inequality and economic insecurity on well-being.

Andrew Sharpe

**GROSS NATIONAL INCOME**

Gross national income (GNI), also known as gross national product (GNP), is an estimate of the value of goods and services produced in an economy. In other words, it is an estimate of the size of an economy. This measure is highly important, having economic, political, and societal implications.

The GNI is defined as the total value of final goods and services produced within a country’s borders in a year, thus the country’s gross domestic product (GDP), minus its net foreign assets. The net foreign assets are composed of the income received from assets owned by nationals in other countries minus similar payments made to foreigners who own assets in the national economy. For instance, if a Japanese-owned company operates in the United States and sends some of its profits back to Japan, then the Japanese GNI is enhanced. However, the repatriation of profit from a U.S. company operating in Japan increases the U.S. GNI but does not affect the Japanese GNI. Hence, unlike GDP, the GNI counts income produced according to who owns the factors of production rather than where it is earned. The conversion from GNI to GDP can easily be done by subtracting the income received from domestically owned goods and services that have been supplied to the production abroad of foreign goods and services. However, the conversion from GDP to GNI requires that one add to GNI the income payments to foreigners for the use of their goods and services supplied to the domestic economy. Thus:

\[
\text{GNI} = \text{GDP} + \text{Net Foreign Assets}
\]

where Net Foreign assets = Foreign Assets – Foreign Liabilities.

The measure of GNI is of great policy significance. GNI, consisting of a basic measure of national income accounting, has been regarded since World War II as an important indicator of the status of the economy. For instance, in the United States the economy is considered to be in recession if GNI decreases during two consecutive quarters. Moreover GNI, as a measure of economic health, is used for the purpose of cross-country comparisons. For example, one defines the importance of an
economy according to the level of its GNI or according to each country's contribution to the world's income production. In addition GNI per person is often used as a measure of people's welfare. Thus countries with high GNI often score high on other measures of welfare.

As previously mentioned, GNI is a function of the GDP. The latter is more common as a measurement of the size of an economy. In some cases the difference between the two measures is negligible. For instance, in the United States the difference between GDP and GNI is only about 1 percent and can be ignored. However, in some countries where net foreign assets' role is significant, GNI is considered to be the most representative quantitative measure of economic activity. This is the case, for example, in Ireland, where in 2000 GDP was 15 percent higher than GNI. In any case, GNI has important policy implications, both at a national level and at an international level (for example, it defines a country's status in an international organization).

GROUPS
A group is a collection of individuals with some degree of interdependence and some element of common or shared identity. Most often, membership in a group involves face-to-face interaction with other members, although such interaction is not a necessary component of a group. (For example, Internet “groups,” which do not involve face-to-face interaction, are becoming increasingly important in the twenty-first century.) Scholarly interest in groups began with sociology's birth. German sociologist Ferdinand Tönnies (1855–1936) made an early contribution when he developed the influential concepts of Gemeinschaft and Gesellschaft to depict two different types of groups related to different kinds of economic and social structures. Gemeinschaft refers to instrumentally-based groups or communities in which social relations are formal and little consensus exists. Gesellschaft refers to small communities in which social interactions are based on friendship or kinship.

The importance of groups and community were also a focus of the French sociologist Émile Durkheim's (1858–1917) writings. For example, in The Elementary Forms of Religious Life (1915), Durkheim discussed the significance of religion for one's sense of belonging. Religion might take different forms in different societies, but all religions stress the importance of social control and cohesion of the group. In this way, the rituals associated with religion serve as visible evidence of the power of the community as they are enacted in a group and for the group.

The American social psychologists Charles H. Cooley (1864–1929) and George H. Mead (1863–1931) both frequently addressed the central importance of groups, especially small groups, and made important contributions to the construction of a framework for understanding symbolic interaction. Cooley, for example, developed the idea of primary groups, that is, groups that are important in intimate interaction. Mead's theoretical conceptualizations in Mind, Self, and Society (1934), including the centrality of groups and the importance of role-taking, were influential in the development of the field of group dynamics.

The German sociologist Georg Simmel (1858–1918) detailed many concepts and perspectives that have preoccupied group theorists since the early twentieth century. His discussion of conflict and exchange framed issues in terms of a dynamic. Simmel argued that exchange was pervasive and that what might at first appear to be purely individual acts are actually influenced by others. To use one of his examples, a teacher teaches, but this involves an exchange with students in part because the teacher considers the students as an audience. People are not isolated agents, acting on their own; rather they act in response to groups.

The study of groups and their structure is sometimes termed group dynamics or group processes. While there are many areas of study within group dynamics, some of the most important are group identity, status, cooperation and competition, exchange, justice, and legitimation.

GROUP IDENTITY
The intensity of identity as a group member varies according to the members' common fate. If membership within a particular group seems to predict important outcomes, group identity may be strong. For example, minorities are likely to feel a strong identity as minority group members because it is evident that their categorization both comes from and creates common experiences.
Collectivities can have elements of common fate, but members may not have group identification and as a result are not usually considered groups. For example, Karl Marx (1818–1883) clearly delineated class interests based upon the means of production; membership in a class was fundamental to life chances. The bourgeoisie controlled the means of production, while the proletariat did not. However, at times, members of those groups may not conceive of themselves as sharing commonalities; in fact, as Marx argued, although members of the proletariat had powerful class interests uniting them, they often lacked the critical recognition of membership in this group. This lack of recognition served the purposes of the bourgeoisie and was an important means of control and power.

Group identity can also be created solely through common experiences, even where no categorization preceded the experience. Experiences such as surviving a hurricane or cancer, for example, can create a powerful group identity among the survivors. Research, especially in the social identity tradition, also indicates that, under some conditions, the slightest form of categorization can function as a type of group identity—strong enough to create in-group favoritism. Research in the area of social identity theory, which developed within European social psychology, emphasizes how individual cognition and group identities are related.

**STATUS**

Status is usually defined as a position in a social network. Importantly, status involves status beliefs, beliefs about the social worth of the individuals who occupy positions within a network such that a person who occupies one position is “better than” a person who occupies another position (Sewell 1992). Early status studies examined the concept of leadership and different forms of group rules that corresponded to different political processes (such as democratic rules versus autocratic rules). In the 1950s, attention turned more to the internal dynamics of groups. The social psychologist Robert Bales (1916–2004) and his associates developed interaction process analysis (IPA), a categorization technique that, in different forms, shaped much of group analysis. In particular, these researchers were interested in how the behavior of one group member conditioned the behavior of others. This idea that status was relative to the group was a central insight and formed the impetus for thinking about characteristics once viewed as fixed (such as sex or ethnicity) as varying in intensity and salience depending upon context.

One of the most developed research programs in the analysis of status is expectations state theory. The theory has several subsets; one of these is status characteristics theory, which concerns how status generates and then sustains inequality of power and prestige within groups. It is posited that this process, called the burden of proof process, is so strong that unless some event or some information intervenes, it organizes interaction consistent with prior evaluations of the status characteristics. In other words, the cultural stereotyping associated with status characteristics are reproduced in different settings and within different groups. Dissolving status hierarchies is difficult because there are layers of group interactions that support and uphold the status quo. However, under some conditions, hierarchies can be dissolved; particularly noteworthy are a series of applied studies in school settings (Cohen 1993).

**LEGITIMATION AND JUSTICE**

Related to issues of status are issues of legitimation, the process through which a principle or set of rules is adhered to even in the absence of incentives. There have been studies of differing sources and processes of legitimation, and particularly promising is research concerning how the granting of power within groups is affected by and reinforced by referential belief structures, or socially validated beliefs at the cultural level that are imported into the local setting.

Other research has addressed how conflict between different sources of legitimation might affect interactions and the establishment or disruption of norms and routines. There is a large literature that aims to answer how individuals make assessments of justice based on their own and others’ benefits. The sociological contribution to justice is the extension of the justice concept beyond the specific individual. Referential belief structures, for example, serve as an external comparison by which to judge the fairness of local settings.

**EXCHANGE**

The social aspects of exchanges are central to the study of groups. Some of the early sociological formulations were patterned after economic models, while others were patterned after behavioral psychology. Sociologist Richard Emerson (d. 1982), relying on behavioral models as a foundation, developed a conceptual framework that viewed the exchange, rather than individual actors, as the unit of analysis. This formulation took the power-dependency relationship among actors or groups as the determining factor in dictating interaction. For a given relationship, the more powerful the actor (whether that actor is an individual or a group), the less dependent the actor. According to Emerson, this power dependency leads to a continual “balancing,” so that the actor who has the most power uses it (because it is to that actor’s advantage to do so), but such use of power leads to some loss of power. This shift in power leads to balancing or sets of strategies by which actors try to retain their power. Theories developed after this initial formulation sometimes refuted the
idea that power was lost. This seems to be especially true in settings in which the social network provides some actors with particularly advantageous positions.

Work on coercive power indicates that in small groups (and perhaps in large groups as well), coercive power (in the sense of punishing others) is a risky strategy because it can decrease the possibilities of future exchanges. Of course, the risk to the coercer is related to the alternatives present for the coerced. Relatedly, the conflict spiral, a theory about bargaining processes, predicts that unequal power, even without punishment, can produce negative emotion.

COOPERATION AND COMPETITION

One of the longest traditions in the study of groups is the investigation of cooperation and competition. The form and type of incentives that encourage or discourage competition have been extensively examined. These incentives might be material rewards, such as money, or social rewards, such as honor or friendship. Even when the incentives are structured so that all might be better off cooperating, cooperation does not always obtain. This is because even in simple settings, coordination can be problematic.

Social dilemmas, settings in which individual and group incentives conflict in some way, are prominent research areas because they are pervasive in many different aspects of life. Such dilemmas range from the small and intimate (e.g., how to maintain a clean house), to the large and relatively anonymous (e.g., how to maintain biodiversity). Many solutions to social dilemmas involve changing the incentives and thereby changing the structure. These might involve punishments for not cooperating or rewards for cooperating.

Other solutions have focused upon social factors arising from group interaction. Two powerful such factors are group identity and trust. If, for example, one actor trusts another to cooperate and then acts on this basis, the dilemma can sometimes be solved. Group identity, as mentioned, can arise from cooperation. Once born, group identity can also lead to cooperation.

GROUPTHINK

Irving Janis (1972, 1982) originated the term groupthink to describe a set of definitive beliefs and behaviors found in decision-making groups when their motivation to maintain internal consensus overrides their rational appraisal of information. The model was developed from qualitative case studies of the flawed decision processes that preceded U.S. government fiascoes like the failure to protect Pearl Harbor against Japanese invasion in 1941, the Bay of Pigs invasion of Cuba during the Kennedy Administration, and the burglary of the Watergate complex during the Nixon Administration. The attractiveness of the model rests largely on its explicit attention to seven antecedent conditions and eight associated patterns of ingroup cognition and action that can influence the quality of solutions to business and organizational problems. The

GROUPS, NONCOMPETING

SEE Noncompeting Groups.
principal antecedent condition of groupthink is extreme in-group cohesiveness. Other antecedent conditions linked to in-group cohesion include insulation of the group from outside information and critics, directive leadership, a lack of group norms prescribing methodical problem-solving procedures, homogeneous attitudes or values among members, high stress due to external competition or threat, and a temporary loss of self-esteem produced by recent failure or the complexities of the task at hand. According to the groupthink model, these contextual antecedents lead to specific psychological symptoms shared by decision-makers that result in a detrimental tendency to seek premature concurrence. The symptoms show up as an illusion shared by group members that they are invulnerable to bad outcomes, an unquestioned belief in the moral superiority of the in-group, an inclination to collectively rationalize support for the group’s decisions, stereotyping of out-group members as weak and wrong, self-censorship through the withholding of dissenting opinions, a perception that other in-group members are unanimous, direct pressure on dissenters to conform, and the emergence of “mindguards” whose role is to protect the group’s preferred position from counterargument. Janis expected this constellation of biased reactions to cause critical flaws in the procedures group members adopt to solve important dilemmas.

The specific errors of group process that are thought to be caused by groupthink include the incomplete review of decision alternatives, inadequate consideration of how proposed actions fit group objectives, failure to examine the negative risks of proceeding with proposed actions, insufficient search for and review of available information, failure to reexamine previously rejected alternatives, and failure to develop backup contingency plans. Researchers generally agree that these procedural shortcomings can reduce decision quality (Baron 2005). However, empirical studies that directly test the effects of Janis’s antecedent conditions on the other components of the groupthink model reveal the risks inherent in developing general propositions from narrative case studies.

SUPPORT FOR THE THEORY

Statements made by NASA officials and consulting engineers at Morton Thiokol just prior to the disastrous 1986 decision to launch the Challenger shuttlecraft were content analyzed in one of a handful of quantitative case studies that show some support for a negative association between specific symptoms of poorly functioning groups (e.g., self-censorship and directive leadership) and decision-making (Esser, 1998). However, these studies also fail to verify essential causes of bad decisions that are specific to the groupthink model. Empirical justification for retaining group cohesion as a key variable in groupthink is especially elusive. Controlled studies designed to experimentally test the effects of group cohesion on groupthink symptoms and outcomes show results that are inconsistent and sometimes contrary to the theory’s primary predictions (McCauley 1998). One reason is that while Janis defined group cohesion as a high degree of attraction or esprit de corps between group members, premature concurrence can also be attributed to a fear of rejection by in-group members or a fear of losing status, especially when self-censorship and directive leadership are involved. In sum, critics argue that groupthink theory is based on a selective sample of cases. Retrospective case studies are an inadequate means of establishing necessary conditions and sound explanations for behavior.

Despite the vagaries of interpreting tests of the groupthink model, there is little doubt that research in this area has revealed a number of reasons why groups may fail to achieve optimal decisions. Pressure to conform to a seemingly popular group decision can follow from pluralistic ignorance, which is a false assumption by individuals that other in-group members are unanimous in their beliefs or knowledge. Likewise, false uniqueness is the sense that one is without support for dissenting from what is apparently the group’s position. When group members are able to discuss their preferred decisions, group polarization can foster confidence that the popular group decision is correct even if all relevant information has not been considered. Finally, extreme group positions may indicate ethnocentrism, which reduces consideration of alternative positions, particularly those that would lead to relationships with out-group members.

GROWTH ACCOUNTING

Growth accounting describes the growth in the total product (output) of an economy or industry by decomposing it into its underlying determinants. This idea is very closely related to productivity growth (or technical change), typically defined as the amount of output growth not accounted for by its identifiable determinants, a residual often called a “measure of our ignorance” (Abramovitz 1962).

The economic building block underlying growth accounting is the production function $Y = f(X,t)$, where $Y$ is output (total production of goods and services), $X$ is a vector (group) of inputs used for production, and $t$ is a time counter. For example, the production function written as $Y = f(K,L,M,t)$ says that the amount of output produced during a particular time period (say, a year) depends on the amount of physical capital ($K$, such as equipment and buildings) used, labor ($L$) employed, and primary and intermediate materials ($M$) purchased.

Based on this production function, and assuming that it represents all factors contributing to production, observed output growth over time can be attributed to (accounted for by) four causes—changes in each of the three inputs ($j = K,L,M$) and the passage of time ($t$, proxying technical change). Formally, this is written as the total derivative $dY/dt = \sum_j \partial Y/\partial X_j \cdot dX_j/dt + \partial Y/\partial t$.

Usually this expression is written in proportional terms by taking the derivative in logarithmic form, as $d\ln Y/dt = \sum_j \partial \ln Y/\partial \ln X_j \cdot d\ln X_j/dt + \partial \ln Y/\partial t$, so each term becomes a percentage change. To then measure productivity growth or technical change (the percentage of output growth not accounted for by changes in input use), this expression is inverted to read $\partial \ln Y/\partial t = d\ln Y/dt - \sum_j \partial \ln Y/\partial \ln X_j \cdot d\ln X_j/dt$, so the left-hand side of the expression, productivity growth, captures growth in output not accounted for by the measured inputs.

Two primary implementation issues immediately arise for measuring these expressions. First, $d\ln Y/dt$ and $d\ln X_j/dt$ are simply data; assuming one has valid measures of real (not nominal) output and inputs, these are just the percentage changes in these measures between two time periods. However, $\partial \ln Y/\partial \ln X_j$ is defined as the change in output from only changing $X_j$, which is not evident from actual data. Second, many other potentially measurable factors that contribute to output growth should not just be lumped into a residual, because that seriously limits its interpretability. For example, research and development (R&D) may be a specific cause of greater production from given input levels, which if distinguished separately would facilitate interpreting or explaining the “drivers” accounting for output growth. Further, even for standard factors of production, their measured changes may not reflect quality variations (say, education of laborers), which one would want to recognize to explain output growth patterns.

The first issue is typically dealt with by the theoretical assumption that firms maximize profits, which implies that inputs are paid the value of their marginal products (for example, a manager is willing to pay a worker up to the amount of money his labor generates). More formally, this means the input revenue share $S_j = p_j \cdot X_j/Y$ (where $p_j$ and $p$ are the prices of $X_j$ and $Y$, so $p X_j$ is the total amount of money paid to input $j$ and $p Y$ is the total value of output) can be substituted for $\partial \ln Y/\partial \ln X_j$. The growth accounting expression then becomes $d\ln Y/dt = \sum_j S_j \cdot d\ln X_j/dt + \partial \ln Y/\partial t$. Although this substitution is based on restrictive assumptions such as full equilibrium and perfectly competitive markets, it means all the components of the growth accounting expression are measurable directly from data on output and input levels and prices (in contrast to econometric estimation).

The second issue is somewhat more difficult to deal with, because even if factors such as R&D are included in the production function, there is no measurable “value” or “weight” for their productive contribution, such as the share paid to an input ($S_j$). That is, if the production function is written as $Y = f(X,R,t)$ (where $R = \text{& R&D}$), the growth accounting expression becomes $d\ln Y/dt = \sum_j S_j \cdot d\ln X_j/dt + \partial \ln Y/\partial \ln R \cdot d\ln R/dt + \partial \ln Y/\partial t$. This equation states that the percentage total output growth observed in the data is explained by the cost share of each of the $j$ inputs multiplied by its percentage change, the marginal contribution to production of R&D multiplied by its percentage change, and the passage of time (trend). However, there is no measurable weight to substitute for $\partial \ln Y/\partial \ln R$ without econometrically estimating the production function. Similarly, there is no clear way to separately identify changes in the quality or characteristics of the $j$ inputs.

Early research in the growth accounting literature initially adjusted measures of capital and labor inputs by measures of quality or composition changes to put them in “effective” units. For example, Dale Jorgenson and Zvi Griliches (1967) “explained” the large productivity growth residual found by Robert Solow (1957) by direct adjustments of capital measures. The typically ad hoc nature of such adjustments, however, caused disputes among researchers about appropriate adjustment methodologies.
Additional issues arose from the more detailed growth accounting models of researchers such as Edward Denison (1979, 1985) and John Kendrick (1979), who included many additional potential growth drivers such as R&D, scale economies, capital obsolescence, and allocation, environmental, and “irregular” factors (such as weather). The multitude of factors that may affect output growth are, however, virtually impossible to measure and weight reliably and consistently for the growth accounting measure. Methodological problems emerging from the limited theoretical and empirical bases of many of the adjustments thus raised serious questions about their validity.

Due to these measurement and consistency issues, detailed growth accounting models have rarely been implemented recently, although this literature has provided the methodological foundation for growth accounting–based productivity or technical change measures. The focus of such studies has been identifying as carefully as possible the various inputs one can measure and find cost share weights for, so the components of the measure can be calculated without econometric estimation.

GROWTH CURVE ANALYSIS

Growth curve analysis, or trajectory analysis, is a specialized set of techniques for modeling change over time. The time frame might be seconds in a psychophysiology study, or years or even decades in a longitudinal panel study. Growth curve analysis is a data reduction technique: it is used to summarize longitudinal data into a smooth curve defined by relatively few parameters for descriptive purposes or further inquiry. It is especially useful in developmental psychology research, measuring intraindividual change over childhood years or life course, but it can also be used to measure change at group levels in sociology or demography. Discussion in this entry will be in terms of intraindividual change, for ease of communication, but the principles apply to other levels of change.

Before the advent of growth curve analysis, longitudinal analysis usually focused on timepoint-to-timepoint relations, or even cross-sectional relations involving different cohorts of participants (and often still does, of course, depending on the nature of the data collection and research question). With only two timepoints of data collection, longitudinal analysis is largely limited to correlation or regression (either predicting an outcome from earlier variables, including the earlier score on the outcome, or predicting a change score). If the researcher has data from at least three measurement occasions, growth-curve analysis becomes a useful tool.

The core idea of growth curve analysis in longitudinal data is that the researcher can estimate a best-fit line or curve to each individual’s responses over time. In subsequent analysis steps, the parameters defining those curves can be analyzed. To take an example of the simplest case, consider reading-competency tests administered at ages six, seven, and eight. With three measurement occasions, growth curve analysis involves estimating a best-fit line (and a residual or error component). The line for each respondent is characterized by an intercept or overall level and slope or linear change over time. In this example, the intercept would typically be set at age six, with the slope representing the rate of change through age eight, as shown in Figure 1 and discussed further below. The means of these intercepts and slopes represent a sample-average trajectory, and the variances of those parameters across individuals represent the variability in the growth curve (line). The individual variation in growth curves can then be predicted from respondent-level variables (e.g., gender, socioeconomic status, treatment condition). If the data collection includes at least four measurement occasions, more complex growth curves can be estimated—for example, with a relation with a quadratic component of time (time squared) in order to model curvature, or acceleration.

ESTIMATION TECHNIQUES

There are two primary analysis techniques for growth curve analysis: multilevel modeling (MLM) and structural equation modeling (SEM). Multilevel models, also known as hierarchical linear models, mixed models, and other terms, are based on the disaggregation of the model into
multiple levels of explanation. For growth-curve analysis, this typically involves a within-person level and a between-person level. The outcome is measured at a within-person level, across multiple occasions. The outcome is directly predicted by an intercept and a time variable or variables. It can also be predicted by time-varying covariates (e.g., teacher qualification) that the investigator wishes to separate from the growth curve. The regression coefficients associated with some or all of these variables are, in turn, predicted by variables at the between-person level. In the example above, there is a person-level equation for each child—a best-fit regression line fitted to the three points. The intercept and slope of this line vary between children. This variance can be predicted by child gender or other between-person predictors.

Structural equation models are used in the specific case of growth-curve models known as latent trajectory analysis. In this instance, the growth parameters (intercept, slope, etc.) are modeled as latent variables that have the individual measurement occasions as indicators. The loadings of the indicators on the growth variables are typically fixed as functions of time, as shown in Figure 1. Reading ability at age six is a function only of the intercept (the value of the intercept for that child multiplied by the loading of 1). Age-seven reading scores reflect the intercept (again multiplied by 1) plus the slope multiplied by 1; at age eight the slope value is multiplied by 2. Thus the slope is the estimated rate of improvement from one year to the next. Finally, as in multilevel models, the latent growth variables can be predicted by other variables in the model.

It is possible to estimate the same models in SEM (modeling means and intercepts, in addition to variances and covariances) as in MLM. In the most common applications, the only differences are in the handling of the occasion-specific residuals, and those differences can be resolved. MLM has the advantage that certain statistics are commonly output that can be useful, such as the apportionment of variance between the two levels. It is also possible to create elaborate nesting structures (e.g., occasion within person, person within classroom, classroom within school, etc.). SEM approaches have the advantage of greater flexibility in the modeling approach. For example, it is possible to model the slopes as dependent on the intercepts, and it is relatively simple to incorporate a second or even third growth process in the same model. Also, characteristic of SEM, the indicators of the growth curve can themselves be latent variables, measured by observed indicators taken over time.

In either approach, it is not necessary that all respondents have the same occasions of measurement. As the key variables are the growth parameters, it is not critical that the growth parameters be estimated for different respondents in exactly the same way—if a child’s reading is measured at age 7.5, the slope value would merely have a loading (multiplier) of 1.5 to characterize the time elapsed since the intercept. As a consequence, even in a fixed-occasion design, the methods easily accommodate missing data collection points, insofar as the missingness is at random (MAR). The consequence of fewer measurement points for an individual is simply that that individual’s data contribute less to the solution of the model.

EXTENSIONS
Much can be done on the basis of a growth curve analysis. For example, more sophisticated models of change can be estimated, especially in the SEM latent growth framework. The growth curve, while a longitudinal model, is essentially a time-invariant estimate of a respondent’s change over time—the curve parameters are constant. Typically, of course, there will be deviations from that curve, because it is, by necessity, a simplification of the data (three data points can rarely be exactly defined by two parameters). One way to model that deviation is by the autoregressive latent trajectory (ALT) presented by Kenneth Bollen and Patrick Curran (2003). In this model, the time-invariant elements of change (intercept and slope) are modeled by the growth curve, while time-specific deviations from the curve (the extent and direction in which measured values differ from predicted values) are predicted in an autoregressive model, where each timepoint is linearly predicted by previous points, so that deviations propagate through time.

Hypotheses about the interrelations over time between two variables are common in developmental research. Historically, these have been typically studied in an autoregressive cross-lagged path analysis model (i.e., a model in which each variable at each timepoint is affected by the previous measurements of both the same variable and the other variable). This can be extended with growth curve analysis to a bivariate ALT, where the relations among the growth parameters of each process are modeled.
according to hypothesis, and the time-specific change in one variable is influenced by the other variable as well.

APPLICATIONS
Two major applications of growth curve analysis beyond the descriptive aspects discussed so far are in analysis of intervention effects and in estimation of predictive models. Continuing the example, in a growth curve in an intervention study to improve reading ability, it is possible to estimate a curve with one intercept and two slopes (or higher-order curves), in which the value of the second slope is constrained to zero for each child in the control condition, and is added to the model for children in the treatment condition beginning with the timepoint after initiation of the intervention. In this case, the first slope represents the baseline growth, and the second slope represents the deviation from the baseline trajectory induced by the intervention.

A second interesting application is the development of predictive models. If the growth curve is well established in observed data, it is possible to project the curve beyond the observed data and make reasonable predictions of future events. Of course, this includes the risk common to any regression model in which prediction is extended beyond the observed range of predictors, but applied with caution, it can be a highly useful tool.

GRUTTER DECISION
Grutter v. Bollinger (2003) was an attempt by the U.S. Supreme Court to define the acceptable boundaries of university affirmative action programs. While setting limits on the design of such programs, Grutter, along with Gratz v. Bollinger (decided the same day), upheld the practice generally and answered some existing questions about allowable techniques.

Prior to these cases, affirmative action law followed California v. Bakke (1978). Bakke, however, confused college admissions officers because six separate opinions were produced, none of which garnered a majority of the Court’s nine votes. Many legal commentators supported Justice Lewis F. Powell’s (1907–1998) opinion as the precedent around which programs should be formed. His opinion upheld diversity in educational institutions—but not correction of past harms—as an acceptable public goal, while limiting the options available to achieve diversity. In particular, Bakke has been interpreted to mean that racial quotas are unconstitutional. However, due to the overlapping opinions, universities and federal circuit courts were unclear about which practices remained acceptable. Some states, therefore, were forced to abandon affirmative action completely, while others encountered a more permissive environment.

Arising in this context, Grutter and Gratz involved the University of Michigan Law School and undergraduate admissions offices, respectively. Grutter left the Law School admissions practice intact, while Gratz found the undergraduate process flawed. Together, the cases upheld affirmative action, while imposing limits on its implementation.

Constitutional jurisprudence has applied “strict scrutiny” analysis for state-sponsored activities that treat “suspect classes” (i.e., groups who tend to experience discrimination) differently. Strict scrutiny first requires that the policy in question be used to forward some compelling state interest. Grutter affirmed diversity as a worthwhile goal of state-funded educational institutions. Second, to survive strict scrutiny, a policy must be narrowly tailored to meet that interest. Quota systems, therefore, remained unconstitutional, and universities were required to make a good-faith effort towards race-neutral policies to further their goals. At Michigan Law School, “plus factors” granted to underrepresented minorities were deemed sufficiently narrow to avoid racial discrimination. This format was accepted as a means of making admissions decisions about individuals rather than seeing them merely as representatives of their racial group. The undergraduate admissions program was invalidated because of the weighting it gave simply for group membership. Justice Sandra Day O’Connor also expressed hope “that 25 years from now, the use of racial preferences will no longer be necessary to further” the interest of diversity.

Future jurisprudence, particularly in light of Justice O’Connor’s retirement in 2006, may revisit the issue and alter the Grutter approach. For the time being, in response to Grutter, some state universities have resurrected affirmative action programs that were locally banned after
In order to comply with *Grutter* and *Gratz*, others have dropped point-based systems in favor of more individualized application review. Michigan, for instance, has moved to a system based on essays about the applicant’s diverse experiences. Although such changes are popular, they require additional admissions staff and financial resources.

Some legal confusion persists, leading risk-averse universities to question whether other diversity efforts, such as minority scholarships, may be at risk. In addition to compliance efforts, *Grutter* has had other political consequences. Most notably, opponents have introduced ballot initiatives to block affirmative action programs. Nonetheless, *Grutter* affirmed the constitutionality of racial preferences in university admissions, significantly reducing previous uncertainty.

**GUANTÁNAMO BAY**

Guantánamo Bay, Cuba, has played a critical role in U.S. foreign policy since the nineteenth century. The U.S. Naval Station there is the oldest American base outside of the continental United States, and the only U.S. base located in a country with which the United States does not have diplomatic relations. Known alternately as GITMO, the 45-square-mile base is located at Cuba’s southeastern tip and is approximately four hundred miles from Miami, Florida. In 2006 GITMO was home to approximately 8,500 U.S. service personnel (and their dependents) whose mission includes providing logistical support to the U.S. Navy and Coast Guard, maintaining migrant operations, and hosting the Detainee Mission of the “War on Terror” under the direction of the Joint Task Force Guantánamo.

American presence began when the United States invaded Guantánamo Bay and established a marine base during the Spanish-American War. Cuban independence fighters worked with American forces to expel Spain. At the end of the war in August 1898, the United States controlled Cuba. The 1901 Platt Amendment, adopted by the U.S. Congress and incorporated into Cuba’s constitution, defined U.S. involvement in Cuba’s affairs. Until such time as Cuba had an independent government, the United States would intervene to preserve Cuban independence or to maintain “a government adequate for the protection of life, property, and individual liberty.” The amendment also ceded Guantánamo to the United States.

After Cuba’s independence in 1903, the Cuban-American Treaty stipulated that the United States would lease Guantánamo Bay as a coaling and naval station. The lease gave the United States “complete jurisdiction and control” of the territory while recognizing “the continuance of the ultimate sovereignty of the Republic of Cuba.” Guantánamo Bay’s unique status was born. The Platt Amendment was annulled in 1934, and the Permanent Treaty codified the leasing arrangement, specifying that the United States would pay an annual sum of approximately $4,085. Since the Revolution of 1959, the Cuban government has accepted only one payment for the lease of Guantánamo, in the first year after the Cuban Revolution. By its own terms, the lease can be abrogated only by mutual agreement. The Cuban government maintains that the base constitutes an unlawful military occupation resulting from an agreement forcefully imposed on Cuba.

In 1964 Cuban president Fidel Castro cut water and supplies to the base hoping to compel U.S. withdrawal. Instead, the base became self-sufficient for its own water and energy. American personnel have been evacuated temporarily from Guantánamo on two occasions: during the Cuban Missile Crisis in 1962 and in 1994, as the population exceeded 40,000 when the base became a holding facility for Haitian and Cuban migrants seeking refuge in the United States. The base continues to serve as an ongoing migrant processing facility, capable of accommodating 10 people, or 10,000 in an emergency.

After September 11, 2001, the base’s mission expanded to include the Detainee Mission of the War on Terror. Beginning in 2002, more than 600 prisoners from approximately thirty countries were brought by the United States to Guantánamo from Afghanistan. The detainees were suspected of having ties to either the Taliban or Al Qaeda, and they were held indefinitely, without charges, without counsel, and without access to American courts. The detainees’ legal status and treatment have been a matter of grave international concern. In 2007 approximately 385 detainees remained imprisoned in Guantánamo.

The U.S. government first posited that the detainees were not subject to the jurisdiction of U.S. courts because Guantánamo was not part of the sovereign territory of the United States. Second, the government consistently held that the detainees in Guantánamo were “enemy combatants.”
ants” and thus beyond the protections provided to Prisoners of War under the Geneva Conventions.

In summer 2004 the Supreme Court held in *Rasul v. Bush* that the United States exercises “complete jurisdiction and control” over Guantánamo under the 1903 treaty, even though Guantánamo is under the “ultimate sovereignty” of Cuba. Hence, the detainees had the right to be heard in U.S. courts. As a result, the U.S. government instituted military tribunals to determine whether the detainees were enemy combatants. These tribunals lacked fundamental constitutional protections guaranteed in U.S. courts.

In 2006 the Supreme Court heard the case of Salim Ahmed Hamdan, Osama bin Laden’s former driver, who had been detained at Guantánamo since 2002. In *Hamdan v. Rumsfeld*, the Supreme Court found, by a vote of 5-3, that the president overstepped his powers by authorizing these military tribunals, which lacked essential legal and constitutional safeguards. Additionally, the Court held that the tribunals violated the Geneva Conventions, rejecting the Bush administration’s argument that the Conventions did not apply to the detainees at Guantánamo. However, the Court did not require Congress to apply the Geneva Convention to the war on terror.

Late in 2006, the U.S. Congress passed the Military Commissions Act, eliminating the right of *habeas corpus* for enemy combatants, allowing the admission of coerced evidence, and giving the president the power to define who is an enemy combatant. The Act does, however, give detainees fair notice of the charges against them, counsel paid for by the American government, and considerable discovery of the prosecution’s case against them. In March 2007, the military tribunals in Guantánamo recommenced with high profile cases resulting in a number of guilty pleas. At the same time, skepticism from left-wing politicians regarding the proceedings grew with increasing calls for the closing of the Gitmo detention center.

Most notably, Robert Gates, who replaced Donald Rumsfeld as secretary of defense in 2007, reportedly called for the closing of the detention center because of concern that the prosecution of war on terror was burdened by the proceedings and their perception by foreign nations. The U.S. Supreme Court may be compelled to address the constitutionality of the Military Commissions Act.

**GUERRILLA WARFARE**

Guerrilla warfare relies on hit-and-run tactics by highly mobile, lightly to moderately armed units that feature deception, speed, and flexibility. Usually conducted by indigenous antigovernment forces, not the regular armed forces of a state, its characteristic attacks include ambushes, raids, sabotage, and blocking of enemy lines of communication. Examples of guerrilla warfare, such as in Iraq and Afghanistan since 2003, increasingly feature the use of road mines and suicide attacks. Guerrilla warfare is classically considered a weapon of the weak to fight a much stronger enemy, such as the state, an occupier, or a colonial power, and is directed not so much at defeating the enemy’s regular forces on the battlefield as at eroding the enemy’s will and capacity to sustain its control.

The first documented record of this kind of irregular warfare occurs on a Hittite parchment from fifteenth century BCE. Since then it has been used among others by the Gauls against Julius Caesar’s (100–44 BCE) Roman army, the Incas against the Spanish conquerors, and the Apache Indians in the U.S. Southwest. Guerrilla warfare became especially prominent during the twentieth century and may be increasingly seen in the twenty-first century, reflecting the great asymmetry in the physical capabilities of the military establishments of modern industrialized states and those of anti-state and revolutionary movements.

Secure bases, internal or external sanctuaries, and good intelligence are important ingredients for the success of guerrilla warfare, as is popular support for the insurgency. It is vital for the success of the guerrillas that the larger population of the area being contested, at minimum, acquiesce to guerrilla activity. In fact, winning the hearts and minds of the people is frequently the goal of both the guerrillas and the anti-guerrilla forces. When guerrillas are able to secure the support of the larger population and are hidden or protected by it, anti-guerrilla forces find it difficult to distinguish between friends, foes, and neutrals and easily slip into punishing the entire population to deter it from supporting the guerrillas. In a
famous case in South Vietnam, a U.S. officer seeking to deprive the Viet Cong of its sanctuary ordered an entire village to be burned, commenting that “we had to destroy the village to save it.”

The success of Mao Zedong’s “people’s war” has served as a model for modern guerrilla warfare for many other guerrilla leaders and counterinsurgency theorists. Mao transformed guerrilla warfare from operations that involved only irregular military tactics to warfare that also featured social, psychological, economic, and—crucially—political components. Mao envisioned insurgency as a protracted social and political revolution, where guerrilla warfare was the means to survive in the initial phases of the struggle before a regular conventional army could be fielded and used to defeat the government.

The process would take place in three phases. The goal of the first phase, strategic defensive, was to expand the communist party organization and establish the infrastructure necessary for further development of the revolution. Party workers were to generate public support and infiltrate the state’s political apparatus. The first period was understood to be a long one, with only a limited resort to force to intimidate the population and create a climate of dissent, civil disobedience, and economic unrest. Once sufficient support, or at minimum acquiescence, among the population was achieved, the second phase, strategic stalemate or strategic equilibrium, was to be launched. In this phase the expansion of terrorism into guerrilla warfare would take place and revolutionary administration—more capable than that of the government—would be established. Finally, in the third phase, strategic offensive, the balance would have clearly swung in the direction of the revolutionary movement and regular units would be introduced and engage in near conventional warfare while the incidence of guerrilla warfare would decrease. The marked feature of Mao’s concept was the emphasis on political and psychological elements as the key to victory, not simply military factors. Mao’s principles have been applied in many guerrilla struggles since, and not only by communist rebels, including in Malaya (1948–1960), the Philippines (1946–1954), Algeria (1954–1962), Angola (1962–1974), Rhodesia (1972–1980), Oman (1965–1975), and Peru (1980–1994).

The foco theory of insurgency and revolutionary warfare developed as an alternative rural guerrilla approach, inspired by the success of a relatively small number of revolutionaries toppling the Batista regime in Cuba in 1959 and hoping to compress the protracted struggle envisioned by Mao into a swift victory. Among its most prominent theorists were Ernesto “Che” Guevara (1928–1967) and Jules Régis Debray (1940–). In contrast to Mao, who stressed the importance of political structures and in fact the dominance of the political, Guevara and Debray argued that the guerrillas themselves were a fusion of the military and the political authority. Instead of a protracted struggle, they argued that a minimum level of discontent with the government could be translated into conditions favorable to revolution. By military action alone, an elite group could provide the focus, or foco, for the revolution. Inspired by the actions of the elite, progressively greater and greater number of sympathizers, alienated by the corruption and brutality of the state, would attach themselves to the revolutionaries and rebel, thus provoking an even more brutal reaction on the part of the government and alienating even more people. Although foco was applied in Colombia, Bolivia, Peru, Guatemala, and Ecuador throughout the 1960s and 1980s, it proved a manifest failure.

The dismal success record of the foco guerrilla theory contributed to the development of urban guerrilla warfare. Carlos Marighela (1911–1969) was among its most influential theorists. Like Guevara and Debray, Marighela rejected the need for a prolonged preparation for revolution. However, instead of the countryside, Marighela situated the center of the revolution back to the cities. The urban guerrillas would be a small band of highly dedicated individuals, who through the use of terror, such as parcel bombs and ambushes, would provoke the authorities into overreaction, thus alienating the population and creating the revolutionary situation. Actions were to be spectacular and aimed at not just the government but also foreign multinationals, with the intention of weakening the economy. In practice, urban guerrilla warfare becomes rather difficult to distinguish from terrorism. The urban guerrilla approach has been applied, for example, by Michael Collins (1890–1922) during the Irish Republican Army struggle against the British in the 1920s, in the latter phases of the Sendero Luminoso (Shining Path) insurgency in Peru in the early 1990s, in Iraq since 2003, and may likely be a prominent feature of twenty-first-century conflicts.

**GUILT**

SEE *Farsightedness*.

**GULAGS**

The term *gulag* refers primarily to the system of forced labor camps existing in the Soviet Union from the 1920s until the mid-1950s, although it is also used in a more generic sense to refer to later labor camps in the Soviet Union and to similar institutions elsewhere. *Gulag* is an acronym from the Russian phrase *Glavnoe upravlenie lagerei* ("main administration of camps"). The gulag played a key role during the dictatorship of Joseph Stalin as both a source of labor for the Soviet Union’s industrialization drive, and a means of removing from society those deemed undesirable by the Soviet state.

The gulag incarcerated around twenty million people in total between the late 1920s and the early 1950s. The number of inmates in the gulag was a matter of fierce scholarly debate during the cold war, but with the opening up of Russian archives beginning in the early 1990s, a broad consensus has been reached, although precise figures remain a matter of dispute, depending on which categories of imprisonment are counted as part of the gulag. Twenty million represents the total number of individuals in the gulag during the Stalin era; the highest gulag population at any given time was just over two and a half million, in 1952.

A Soviet Politburo decision of June 1929, “On the Use of the Labor of Convicted Criminals,” marked the beginning of the widespread use of forced labor to contribute to the national economy, and coincided with Stalin’s drive for rapid industrialization of his largely rural country. The growing gulag camp network provided a means of forcing the millions of people thrown off the land during the collectivization of agriculture to be used in the cause of industrialization, chiefly plant and infrastructure construction and the development of remote areas rich in raw materials. Soviet economic plans included targets for gulag production, and the prisoner population grew inexorably, interrupted only by World War II, to its peak in the early 1950s. Judicial procedures were cursory and entirely subject to the Communist Party, dominated by Stalin.

Living conditions for gulag prisoners undermined the view that they were a valuable labor resource. Rations were poor and used as a reward for meeting output targets. In some periods, particularly around World War II, starvation and disease were rife.

Following Stalin’s death in 1953, his successor Nikita Khrushchev authorized the rapid winding down of the mass gulag system. At first celebrated as enlightened, “corrective labor” by the Soviet authorities in propagandistic films and books, the gulag system was shrouded in a veil of official secrecy from the late 1930s until the Khrushchev years. In 1962 the publication of Aleksandr Solzhenitsyn’s *A Day in the Life of Ivan Denisovich* caused a sensation and marked the height of the relative cultural thaw of that time. A decade later, with the more conservative Leonid Brezhnev in power, Solzhenitsyn’s *Gulag Archipelago* (1973) had to be published abroad. Solzhenitsyn (b. 1918) was awarded the Nobel Prize for Literature in 1970; in 1974 he was deported from the Soviet Union and stripped of his citizenship. In the post-Soviet era, the fate of gulag prisoners has been written about widely in Russia and abroad; memorials have been raised, though there is still no single central memorial, and independent groups, often made up of survivors and the relatives of victims, have sought to keep the memory of the gulag alive.

GULF STATES

The six nations that formed the Gulf Cooperation Council (GCC) in 1981—Saudi Arabia, Kuwait, Bahrain, Qatar, the United Arab Emirates, and Oman—are all oil-producing monarchies. Until a few decades ago, they were among the poorest countries in the world. Since the discovery of oil and particularly the oil price revolution of the early 1970s, the six have been able to carry out massive programs of socioeconomic development that have dramatically increased the per capita income of their citizens, resulted in a huge immigration of foreign workers, strengthened the control of ruling families over the states, and thrust the members into the international spotlight. Saudi Arabia is by far the largest of the group with a population estimated at 27 million. The other five range in size between 700,000 and 3 million.

Saudi Arabia has emerged as a major actor in Middle Eastern affairs. It has provided aid to and supported various Arab governments, even those with which it is ideologically odds. It has valued its “special relationship” with the United States and has supported U.S. policy aims in various parts of the world, despite fundamental differences over U.S. policy regarding Israel. The smaller five states have also sought to follow a neutral path in regional differences, although they were all alarmed by the Iranian revolution of 1979 and supported Iraq in its 1980–1988 war against Iran. But Iraq also proved to be an aggressor when Saddam Hussein’s troops invaded Kuwait in 1990, requiring a U.S.-led international coalition to dislodge him. The GCC states also opened up their military facilities to provide assistance to the U.S.-led coalition attacking Iraq in 2003, although many of their citizens disagreed with the action.

A principal impetus for the creation of the GCC was to assure the security of its members in a volatile region. A small joint force was established near the Iraqi/Kuwaiti border and the six states have engaged in numerous joint exercises. However, the GCC members continue to depend heavily on Western assistance and their national armed forces have not been coordinated either in terms of equipment (purchased from a wide variety of countries) or doctrine and training.

But there were other legitimate purposes for the formation of the GCC as well, in which the GCC has succeeded relatively better than in security. Politically, the GCC has seen considerable coordination between the individual states, and many issues are thrashed out in advance of the six rulers’ annual summit. The majority of differences between members have been settled, although some remain. A GCC headquarters and secretariat has been established in Riyadh and the position of secretary-general is rotated between the members.

In the economic sphere, the body has succeeded in standardizing weights and measures, creating a common tariff, assuring the free movement of (indigenous) labor and capital throughout the GCC, and taking steps toward a common currency. The members also have created cultural organizations to exchange information and ideas in such areas as education, professional disciplines, and the arts.

GULF WAR OF 1991

The invasion of Kuwait by neighboring Iraq on August 2, 1990, triggered the first major international crisis of the post–Cold War era. The United States had uneasily supported Iraq during its eight-year war against Iran (1980–1988), a conflict known in the region as the First Gulf War, but Iraqi president Saddam Hussein misinterpreted certain diplomatic signals about whether the United States would acquiesce over this latest military action. Kuwait had also sided with Iraq against Iran, but
Kuwait and Iraq had fallen out over war debts, border disputes, and competing oil prices. When Iraq invaded in 1990, Kuwaiti defenses were quickly overrun and its government fled into exile. Because Iraq now threatened the Saudi Arabian oilfields, the United States spent the next six months assembling an international coalition of thirty-four nations, including regional Arab and Muslim states. The United States also secured ten United Nations resolutions to isolate Iraq and prepare for “all necessary means” to expel Iraq from Kuwait by force if it did not withdraw voluntarily. On the night of January 16 to 17, 1991, the U.S.-led “coalition of the willing” launched massive air strikes against Iraq’s command-and-control infrastructure and its antiaircraft defenses. This conflict began under the title Operation Desert Storm.

For the next five weeks, coalition aircraft and missiles degraded the occupying Iraqi army’s capacity to resist a land-war offensive. Iraq tried to expand the conflict and split the Arab members from the coalition by firing Scud missiles at Israel. The Iraqi air force fled to Iran after the loss of thirty-eight of its planes, giving the coalition air superiority for the rest of the war. Iraq released crude oil into Persian Gulf waters and even, briefly, occupied the Saudi coastal town of Khafji. Coalition “strategic” bombing missions were largely confined to Iraqi military forces and targets, while a new generation of “smart” missiles hit their military targets with unprecedented accuracy. Some “collateral damage” did occur, when some missiles missed their intended targets, causing unintentional damage and casualties and also causing intense media debate in the new age of real-time reporting around the clock by the Cable News Network (CNN). The two most controversial incidents were the bombings of an alleged baby-milk plant and the Al Firdos installation in Baghdad. The coalition insisted the baby-milk plant was really a chemical weapons facility and the Al Firdos installation was a command and control facility rather than a civilian bomb shelter as the Iraqis maintained. Around 400 civilians were killed on the occasion of the latter. The presence of journalists from coalition countries in the enemy capital while Iraq was under fire was unprecedented and made the propaganda war more complex.

The ground war began on February 24 and lasted barely a week, with Iraqi commanders agreeing to a “cessation of hostilities” at Safwan air base in southern Iraq on March 3. Although Saddam Hussein had promised “the mother of all battles,” the Gulf War was one of the most one-sided conflicts in military history. An unknown number of Iraqi soldiers and civilians died (estimates vary from 25,000 to 200,000) and almost 70,000 Iraqi soldiers surrendered to the coalition, which suffered fewer than 350 dead, the majority of them Americans. Television images of bombed-out Iraqi convoys fleeing Kuwait may have had an impact on the decision to end the war.

In the long term, the war had disastrous consequences: It marked the arrival of Western military forces into the Muslim holy land of Mecca, which prompted the Saudi-born terrorist Osama bin Laden to turn against the United States, which had sponsored him during the Soviet invasion of Afghanistan.

Philip M. Taylor
be accepting of immigrants as (a) citizens in the country, (b) coworkers in the same company, (c) neighbors, (d) close friends, and (e) close relatives by marriage. A tolerant individual would probably endorse each one of these statements in the scale. A less tolerant individual might be willing to accept immigrants as citizens in the country but not as neighbors or close family members. Thus, knowing that a person is not willing to accept immigrants as neighbors allows us to infer that this person probably would not want immigrants as close friends either; accepting them as family members would be even less likely for this person. By knowing the last statement endorsed by a respondent, one can easily reproduce his or her pattern of responding to the rest of the statements. In a perfect Guttman scale, the pattern of responding across the scale can be reproduced without any errors.

When the issue is relatively concrete, such as the amount of smoking, or when the construct is hierarchical in nature, such as social distance, Guttman scales work quite well; however, when it comes to measuring relatively more abstract attributes such as attitudes toward immigrants or marriage, it is not always easy to construct such highly reproducible scales.

As in all methods of scale construction, the first step in Guttman scaling is to generate a large set of items representing the construct. Then, a group of judges (80–100) evaluates each of the statements. Depending on the nature of the construct, the evaluations might be to indicate whether or not they agree with each statement, or to indicate whether the statement reflects the absence or presence of the phenomenon. For instance, if the construct in question is attitudes toward gun control, the judges will try to determine whether each item in the scale (e.g., “future manufacture of handguns should be banned”) is in favor of or against gun control. In the next step, the responses of each judge are tabulated. In this table, the columns represent items in the scale, and the rows represent each judge. Once all the entries are laid out, the table is sorted so that judges who agree with more statements are listed at the top and those agreeing with fewer are at the bottom; then the number of affirmative responses are summed to create a total score for each judge. If the set of items were to form a cumulative scale, then it should be possible to reproduce the responses of each judge from his or her total score. Errors in reproduction indicate deviation from the optimum form, and suggest a call for revision of the scale, which can be done by changing or dropping existing items or even adding new items. The scale is revised until it becomes possible to reproduce over 90 percent of the responses from the total score. At this point, some statistical analyses can be conducted to examine deviations from a perfectly cumulative scale. These statistics can also be used to estimate a scale score for each item, just as in Thurstone scaling; ultimately, these scale scores are used in the calculation of a respondent’s final score. A final set of items emerges after several revisions. Once the final set of items is established, the order of the items is mixed again to derive the final form of the scale to be shared with actual respondents.

The primary area of application has been in attitudes and public opinion—Guttman constructed a number of attitude scales during World War II using these procedures. Currently, however, as a method of constructing attitude scales, Guttman scaling is almost never used. Investigators prefer to use simpler methods of scale construction such as Likert scaling and the semantic differential technique.

HABERMAS, JÜRGEN
1929–

Jürgen Habermas is a philosopher and a prominent public intellectual in Germany. He is considered the leading representative of the second generation of the Frankfurt School, whose Critical Theory he has sought to reinvigorate in his sustained reflections on social theory. Habermas, however, diverges from his predecessors in his analysis of the emancipatory promise of the Enlightenment, whose political legacy, he maintains, remains unrealized. Drawing on the philosophy of Immanuel Kant, one of the foundational theoreticians of modernity, Habermas perceives a sublated potential in modernity. He posits the realm of communication as a counterweight to the Frankfurt School’s disillusionment with a modernity corrupted by the destructive ascendancy of instrumental reason.

In his first book, The Structural Transformation of the Public Sphere (1962), Habermas demarcates theoretical concerns with public discourse and reason that would animate much of his later writings. This sociological and historical work examines the emergent bourgeois public sphere in Western Europe in the eighteenth century, tracing its origins as a “sphere of private people come together as a public” (1989, p. 27) and the concomitant transformations in modes of communication that it fostered as the new public deployed reason against the contemporary absolutist political order. As he chronicled the subsequent decline of the public sphere, Geoff Eley notes, Habermas was also criticizing the straitened confines of West Germany’s authoritarian postwar political culture of the 1950s and 1960s (Eley 2002, p. 292). Many scholars have engaged Habermas’s thesis, extending his analysis to other settings while also arguing for greater attention to the exclusionary mechanisms that hinder participation in the public sphere (Calhoun 1992, Gilroy 1993, Landes 1988).

Habermas’s Knowledge and Human Interests (1968) is a critique of positivism elaborated through a comparison of social theory and psychoanalysis. Knowledge and Human Interests represents an early iteration of Habermas’s theory of communication, and prefigures the linguistic turn of his magnum opus, The Theory of Communicative Action (1981). Here Habermas argues that the sphere of the everyday, or the life-world, has been progressively “colonized” by instrumental reason. Habermas asserts that the counterbalance to this process must be found in an intersubjective reciprocity arising in the sphere of language, arguing for a distinct communicative rationality in which language coordinates action among subjects as it socializes them. Habermas’s writings on political theory, such as Legitimation Crisis (1973), Between Facts and Norms (1992), or The Inclusion of the Other (1996), anchor a theory of discursive democracy in his analyses of communicative practice in the public sphere. Critics counter that Habermas’s theory of discourse is totalizing, wrongly assuming that all actors ultimately seek consensus as the outcome of their communicative interventions in the world (Lyotard 1979).

In The Philosophical Discourse of Modernity (1985), Habermas turns to the debates about postmodernism, criticizing Theodor Adorno’s negative dialectics, Michel Foucault’s genealogy, and Jacques Derrida’s deconstruction for providing insufficient grounds for breaking free
from the totalizing reason their practitioners’ critique. He holds that the predicament of the transcendental subject that “philosophies of consciousness” pose can only be surpassed in the realm of intersubjectivity.

Habermas has often participated in the public sphere he analyzes in his scholarly writings. He was a leading spokesman for the student movement of the 1960s, and in the 1980s, he intervened in the Historians’ Debate against the attempts of revisionist West German historians to lay the Nazi past to rest. More recently, Habermas has weighed in on issues of European identity and integration.

HABITS

The term habit receives broad and varied usage across branches of the social sciences. According to essentially all definitions, habits are learned, recurrent patterns of behavior that are enacted with minimal reliance on conscious resources or effort. They typically are tied to an environment or another action that historically has co-occurred with the habit and thereby has come to serve as a stimulus, or cue, for its automatic performance. When habit is defined in purely behavioral terms (e.g., as an action performed almost daily and consistently in response to a specific environment), research suggests that around 45 percent of people’s daily life can be deemed habitual (Wood, Quinn, and Kashy 2002).

Disciplines differ substantially, though, over the subset of behavior to which the term is applied. In general, psychological usage focuses on relatively simple, low-level behaviors, including those that benefit the individual (e.g., typing, coffee making, seat belt wearing, and condom use) and those that exact costs (e.g., nail biting, smoking, drug use, and overeating). Within sociology and related disciplines, the term is often applied more broadly to describe any stable pattern of action that is spontaneously reproduced via humans’ preconscious engagement in the world around them. This broader application can encompass habits of social, linguistic, economic, political, religious, or moral conduct, and may involve the performance of even complex forms of action.

A BRIEF HISTORY OF HABITS

Contemporary conceptions of habit draw from multiple historical traditions, including pragmatism, behaviorism, and phenomenology. Early psychological use of the term can be traced most strongly to the pragmatist and behaviorist schools. For pragmatists, such as William James and John Dewey (1859–1952), habits were acquired reflexes that emerged due to the inherent plasticity of the nervous tissue. As a behavioral sequence is repeatedly enacted, the brain matter underlying the action was thought to become ever more predisposed to reproduce the sequence. Physiologically, this process was thought to be sustained through the development of reflex paths (or “reflex arcs”) in the nervous system that linked a sensory cue with a (typically) muscular response. Once established, the habitual response could then be initiated by the sensory cue alone (i.e., without recourse to an idea, will, or volition) and would run off to completion in a ballistic fashion (i.e., each action in the sequence would prompt performance of the next). For William James, this inherent tendency towards the habitual constituted “the enormous fly-wheel of society” ([1890] 1981, p. 121), explaining myriad forms of routine action, from habits of

Krista Hegburg
speech, gesture, and movement to habits of character and even the inertia of social classes.

Behaviorists also viewed habits as learned, stimulus-cued responses, but largely rejected psychological mediators as irrelevant to the explanation and prediction of behavior. Especially for radical behaviorists such as John Watson (1878–1958) and B. F. Skinner (1904–1990), habits were under the direct control of environmental stimuli, and this control was better understood by examining objectively specifiable schedules of reinforcement (e.g., patterns of reward) than by examining mental processes. This stimulus-response model of habit was expanded, albeit unsuccessfully, by Skinner to encompass even verbal behavior.

In contrast to the behaviorists, phenomenologists such as Maurice Merleau-Ponty (1908–1961) and Alfred Schütz (1899–1959) focused on the role habits play in providing a preconscious, taken-for-granted framework that guides people’s interactions with the world around them. Habits, in this sense, reflect a set of action possibilities that present to consciousness as natural and given (e.g., a chair appears to lend itself to sitting), but are actually the product of the individual’s social and embodied action history. Some phenomenologists (especially Schütz) emphasized the role of social experience in the development of this prereflective framework of habit, and his work went on to influence both ethnomethodologists such as Harold Garfinkel (b. 1917) and social constructivists such as Peter Berger (b. 1929) and Thomas Luckmann (b. 1927). The phenomenologists’ emphasis on the embodied dimension of habit (especially Merleau-Ponty’s) also resonates with Pierre Bourdieu’s articulation of *habitus* as a set of bodily dispositions that strategically but unconsciously reproduce past action sequences in a contextually tuned manner.

Despite these broad and differentiated applications, the habit construct lost popularity around the mid-twentieth century due to its close identification with the behaviorist research agenda and its apparent neglect of people’s capacity to plan, deliberate, and reflect upon their actions. As a powerful counterpoint, many social scientists rallied around the idea that human behavior is fundamentally purposive, reflective, and under the control of goals, attitudes, intentions, and conscious rules. Rational choice theorists epitomized this view, and indeed their premise that people act to maximize outcomes in accordance with personal preferences remains a dominant theoretical paradigm in contemporary economics, political science, game theory, and some social theory. Within psychology, the value of the habit construct was also challenged by Martin Fishbein and Icek Ajzen’s influential “theory of reasoned action” (1975), which stipulates that performance of behavior is determined directly by intentions (which, in turn, are said to be influenced by one’s attitudes and perceived norms). By portraying the human actor as a relatively rational, goal-driven entity whose actions are determined by their intended effects, these perspectives left little room for habit as an explanatory mechanism, and the term entered a state of relative hibernation until the 1980s.

**CONTEMPORARY RESEARCH INTO HABIT**

Fueled by advances in cognitive science and a zeitgeist more skeptical of wholly rationalist, reflective views of human action, contemporary social science has returned to the active study of habit. One catalyst has been evidence that people draw on relatively independent (but interacting) psychological systems in the control of action. These systems are variously termed procedural v. declarative, implicit v. explicit, automatic v. controlled, or nonconscious v. conscious. Habits tend to be associated with the first term in each dichotomy, whereas novel, deliberative actions tend to be associated with the second term. The independent nature of these behavioral control systems is compellingly evident when brain damage affects one, but leaves the other intact (Knowlton, Mangels, and Squire 1996). Patients with Parkinson’s disease, for example, are able consciously to remember a complex sequence of cues, but cannot incorporate these cues into routinized habits. Conversely, patients with amnesia will not be able to remember the cues, and yet will successfully acquire habitual responses to them. Such research suggests that habits are grounded in psychological systems that are distinct from those used to guide more deliberative, reflective behavior.

A similar conclusion flows from behavior prediction studies, which identify the psychological states and environmental factors that are associated with performance of a given behavior (Wood, Quinn, and Kashy 2002). Such studies suggest that nonhabits and habits exhibit distinct predictors. Consistent with rationalist perspectives, the performance of novel or newly acquired behaviors (e.g., sticking to a new gym routine) is best predicted by the presence of favorable attitudes and intentions (e.g., a strong positive attitude or intention toward fitness). When a behavior has been repeated sufficiently to become habitual, however, attitudes and intentions become less determinative of continued performance. Instead, habitual behaviors are predicted by the mere presence of contextual cues (e.g., people, places, other actions, time of day) that co-occurred with the behavior in the past. Thus, whereas novel actions are guided largely by people’s plans, desires, goals, and intentions, habits are guided largely by the context provided by preceding actions and the external social and physical environment.
Due to their highly automated, contextually cued nature habits are not readily inhibited or overcome by methods that are effective at controlling more deliberative forms of action (e.g., public information campaigns that alter people’s beliefs or attitudes). Instead, habits may be more responsive to techniques that mitigate or redirect their underlying automatic associations. These techniques include stimulus control (avoiding environmental cues that trigger habits) and counter-conditioning (identifying environmental cues and substituting desired behaviors). That said, habits are notoriously difficult to overcome, and relapse is the modal outcome following many attempts at habit change (e.g., diet change, smoking cessation).

FUTURE DIRECTIONS
Contrary to both strict rationalist and strict behaviorist positions, contemporary social science acknowledges that the human actor can be driven by reflective, goal-directed mechanisms on some occasions and reflexive, habitual mechanisms on others. As discussed, these forms of behavior are subserved by relatively independent psychological systems and neural substrates. That said, research is beginning to address important interactions between the conscious, deliberative dimension of behavior and the nonconscious, habitual dimension. Notably, some sociologists argue that habits are integral to free will and agency insofar as they provide a framework of action possibilities that can be imaginatively reconfigured to meet a person’s current goals and circumstances (see, for example, Emirbayer and Mische 1998). Furthermore, recent work in psychology suggests that habits can be motivated by a very general sense of reward, without necessarily being directed by specific goals (see Neal, Wood, and Quinn 2006). These approaches move away from the earlier sharp distinctions between habitual and deliberative action, and toward a view of human behavior as involving a dynamic interplay of goal-directed, intentional, reflective processes along with automated context-cued habits.

HABITUS

Habitus is a term used by the French sociologist Pierre Bourdieu (1930–2002) to describe a social property of individuals that orients human behavior without strictly determining it. While habitus encompasses a sense of practical expertise, it is not a conscious expertise; rather, it may be seen as common sense. It is constituted of dispositions that are inculcated, structured, durable, generative, and transposable (see Thompson 1991, p. 12). Habitus is a state of the body and of being, a repository of ingrained dispositions that thus seem natural. Bourdieu calls this the bodily hexis, where “the body is the site of incorporated history” (Thompson 1991, p. 13; see also Bourdieu 1984, pp. 437, 466–468). Thus, habitus is purposeful without being questionable; it is transmitted but not actively taught.

Bourdieu presents habitus as a conceptual framework in which there are varying degrees of explicitness of, and competition among, norms. Under this framework, there are three ways that people experience the norms of their social existence. They do so through (1) a set of materially predisposed practices that express a belief about the way the world works and that reproduce that worldview. These predisposed practices tend to produce doxa, situations in which “the natural and social world appears as self-evident” (Bourdieu 1994, p. 160; 1976, p. 118); this is habitus, the unquestioned order of things. People also experience the norms of their social existence through (2) the contrasting situation of orthodoxy, in which “social classifications become the object and instrument of … struggle” and in which the arbitrariness of the current system becomes evident, and through (3) heterodoxy—a situation of more or less equally “competing possibilities” (1994, pp. 164–165). Bourdieu emphasizes the “complicitous silence” of community members in the continuous reproduction of the “collective rhythms,” or habitus, of the community (1994, p. 182).

A tension then exists between the formalized codes that dictate practices and “the generating and unifying principle of practices … constituted by a whole system of predispositions inculcated by the material circumstances of life and by family upbringing” (Bourdieu 1976, p. 404)!
The habitus is “the end product of structures which practices tend to reproduce in such a way that the individuals involved are bound to reproduce them, either by consciously reinventing or by subconsciously imitating already proven strategies as the accepted, most respectable, or even simplest course to follow. [They] … come to be seen as inherent in the nature of things” (1976, p. 118).

Thus, with this concept Bourdieu seeks to demystify the very concept of “natural” and to emphasize the creation of “a second nature” (1991, p. 123). For example, every day we don clothing. While we may think about what to wear, we do not think about whether we will wear something. The conventions of style in dress themselves are nearly as inculcated as dressing. Only within the field of fashion are these styles and meanings routinely discussed explicitly. There are those who challenge the professional fashionista’s (or the everyday women’s magazine reader’s) habitus of style, while punks are known for their ironic appropriation of military uniforms and their practice of making ugliness into beauty (see LeBlanc 1999). Andrew Martinez (Berkeley’s “Naked Guy” from the early 1990s) engaged in a practice of public nudity that sought to challenge the basic habitus of getting dressed at all (see Seligman 1992; Jacobssex 1992; and Jones 2006).

CRITICAL INTERPRETATIONS

Habitus is a process, at once deeply embedded and simultaneously available for analysis; it is often discursively ephemeral, and yet easily accessed and employed. At points in his work, Bourdieu suggests that habitus is quite active, an activity of power of at least some savvy agents:

The work of inculcation through which the lasting imposition of the arbitrary limit is achieved can seek to naturalize the decisive breaks that constitute an arbitrary cultural limit—those expressed in fundamental oppositions like masculine/feminine, etc.—in the form of a sense of limits, which inclines some people to maintain their rank and distance and others to know their place and be happy with what they are, to be what they have to be, thus depriving them of the very sense of deprivation (Bourdieu 1991, p. 123).

For Bourdieu, if one does not understand that what one thinks is natural is actually accreted practice, and practice inculcated from a particular social position, one can never engage in true social change (see Brubaker 1993, p. 217). At the same time, he emphasizes that habitus is subconscious—it is embedded bodily. The question of when habitus does become concerted effort, analysis, or argument (that is, when does the situation of either orthodoxy or heterodoxy arise?) is often inadequately dealt with (see Calhoun 1993, pp. 80–82).

Though habitus is conceived of as deeply embodied and self-evidently nondiscursive, there is a sense that habitus competes across fields—that people can, indeed often must, acquire a particular habitus that they then must apply in particular situations (Calhoun 1993, pp. 77–80). Because Bourdieu uses habitus to deal with the cultural arbitrariness of language and discourse itself (see especially Bourdieu 1991), it is something of a paradox that he asserts its nondiscursive character.

The field of law is a particularly problematic arena when one is considering the place of habitus in social processes. “Predispositions” and the process of naturalization are important in the legal system, but habitus does not easily explain the existence of laws, especially in frontier situations of transition, where there are formative struggles over what the laws should be. This is especially significant in the legal process, where it is explicit that language and discourse are key. Indeed, while social actors may be “subconsciously imitating” and “consciously reinventing” social structures, a struggle is involved. Thus, actors are not necessarily “bound to reproduce” the prevailing images and structures of their community. Formal law has a role to play beyond that of everyday activities and reasoning, although these play a part in forming law. In other words, as Mindie Lazarus-Black argues, “common sense understanding, or … habitus, is generated not only out of small scale networks of practice but also out of the legitimation project of the state.” One function of [this] project is to define the people under its control (creating the external boundaries of the system) and to differentiate between them (creating internal boundaries within the system)” (1994, p. 6).

In terms of the symbolic power of language, there is a sense that actors in public fields such as law are playing to doxa, with a highly crafted and explicit discourse—the sound bites and metaphors of color blindness and racially neutral language, for example, which expose that race is a habit within a system that also acknowledges a doxa of democracy (see Gatson 1999; Bonilla-Silva 2003, pp. 49, 104, 125).

Thus, instead of suggesting that analyzing formal law is useless by stating that it is “unnecessary to make explicit or … invoke or impose any rules,” one should perhaps rather attempt to examine situations in which the struggle to invoke certain rules over others is very explicit (Bourdieu 1976, p. 141). Calhoun argues that Bourdieu’s “sociology does not offer much purchase on the transformation of social systems…. His accounts of the general system of social and cultural organization always render it as essentially conservative … imply[ing] dynamism … at the level of the strategic actor…. [Habitus] is at its best as a theory of reproduction, and at its weakest as a theory of transformation” (Calhoun 1993, pp. 70, 72). But that
weakness is perhaps telling, signaling the inertia of systems, and the need for everyday sociology in the citizenry. For each of us, the habitus is cycle and process. There is a simultaneity of habitus—doxa, orthodoxy, and heterodoxy may be clearly delineated when they are used to describe a macrolevel history of a particular field. As to the everyday, and at points of conflict, the cycle of habitus may be far more difficult to tease apart.

HAITIAN REVOLUTION

The Haitian Revolution (1790–1804) brought political independence to Haiti, the second nation in the Americas to free itself from colonial rule. It also brought freedom to some 450,000 Afro-Caribbean slaves and served as a potent symbol of liberty to millions of their fellows who remained enslaved throughout the Americas. Other independence movements in the Americas at the time, like the American Revolution (1775–1783) or the independence struggles in Spanish America, pitted colonial elites against metropolitan governments and offered little possibility for immediate change in society. The Haitian Revolution, on the other hand, was a true social revolution, which led to remarkable changes in the lives of ordinary people on the island and the colony’s role in the world economy.

THE COLONIAL BACKGROUND

Haiti, known as Saint-Domingue before the revolution, was the richest colony in the Americas in 1789. Almost half a million slaves toiled on its sugar, coffee, indigo, and cotton plantations. More than thirty thousand new
African slaves arrived each year, both to replace the many who died of overwork or disease and also to fuel the rapid economic expansion that the colony experienced in the 1780s. Between a third and a half of all slaves on the island were born in Africa. While the slaves had been evangelized and educated by Jesuit missionaries in the early days of the colony, the Jesuits were expelled from Haiti in 1767. After that, the slaves were left to their own resources, and had developed their own culture, complete with a language, kreyol, and a religion, voudou, both strongly influenced by African models. The slaves were owned and supervised by a population of around fifty thousand free persons, about half of whom were Afro-Caribbean free coloreds. The largest plantations on the island were owned by whites, many of whom were absentee landlords living in France. There was a growing class of poorer whites who hoped to become planters. Alongside the poor whites, there were free coloreds, some of whom owned plantations while others competed with the lower-class whites for plantation management or craft jobs.

Saint-Domingue’s free people, both whites and blacks, despised French mercantilist economic regulations and dealt with smugglers whenever they could. They undermined the colonial government in other ways as well, rebelling against increased military obligations in the 1760s, for example. There is considerable evidence that the wealthier inhabitants of Saint-Domingue were developing an “American” identity in much the same way that wealthy North Americans had done in the period before the American Revolution and that wealthy Spanish Americans did in the 1800s before the independence struggles there.

But Saint-Domingue society was sharply divided on racial and class lines. Racial distinctions between whites and free coloreds were always significant and became even more marked after the 1760s. Some scholars have suggested that this was a calculated “divide and conquer” strategy by the colonial government to drive a wedge between wealthy white and free colored inhabitants. In any case, the racially divided masters of the colony were vastly outnumbered by their slaves. The need to be eternally vigilant against slave uprisings, and the need for French troops to provide the final element of security, made it less likely that wealthy colonists would think of independence in Saint-Domingue—or that poor people could make common cause across the divide of race and status.

THE OUTBREAK OF THE REVOLUTION

But revolution did come. At first, it came as an echo of the revolution going on in France. Both white and free colored planters appealed to the French revolutionary assemblies in 1789. But the French legislatures avoided the questions of slavery and civil rights for free people of color for two years. During this time, political struggles broke out in the colony between white planters and less-wealthy whites. Each side appealed to free colored allies, and the slaves watched everything that was going on.

Two wealthy free colored men, Vincent Ogé (c. 1750–1791) and Jean-Baptiste Chavannes (c. 1748–1791), rose up in rebellion in 1790, calling for civil rights for free coloreds. Their movement was quickly crushed and they were executed, but the first shots had been fired. Free coloreds continued to fight their own struggle throughout the larger revolution that followed, and indeed went on to play an important role in post-independence Haitian society.

REVOLUTION FROM BELOW

The slaves did not need French political philosophers or wealthy free colored planters to tell them that they ought to be free. There had been slave uprisings and other acts of resistance on the island since the first Africans arrived, brought by the Spanish, in the sixteenth century. But rebellions were always crushed by the superior military force of the colonial government. Even the maroons, or runaway slaves, who had hidden in the mountains and lived as free peasants in the early days of the colony were pretty much eradicated by the 1780s, as plantations spread throughout the island. But when the masters fought among themselves, the slaves saw their opportunity.

Slaves with leadership positions, such as coachmen, foremen of work gangs, technical specialists, and hunters, together with voudou practitioners and some free people of color organized a great uprising among the slaves of the northern plain. This area was the most heavily populated and richest area of the colony. The slaves rose up the fourth week of August 1791, burning hundreds of plantations and killing or driving out the masters. The early leaders of the rebellion were slaves, such as Boukman, the organizer of a famous voudou ceremony at Bois Cayman that may have been the signal for the uprising. But the ultimate leader of the slave army was Toussaint Louverture (c. 1743–1803), a pre-revolutionary free black planter and slave owner.

Toussaint’s soldiers fought from 1791 until 1799 against a dizzying variety of enemies: French revolutionary governors, French royalists, English and Spanish invaders, and free colored leaders. In the midst of this struggle, in 1793, the French revolutionary commissioner Léger-Félicité Sonthonax (1763–1813) proclaimed the end of slavery in the colony and Toussaint’s forces became officially part of the French army.
But by 1801 the government back in France was beginning to reconsider the abolition of slavery. Napoléon Bonaparte (1769–1821) was first consul. He needed the wealth of Saint-Domingue and he distrusted freedom. Toussaint had succeeded in taking military control of the island but not at restoring sugar production. The slaves were not interested in working on plantations, even for wages. They wanted to own their own farms. As the manpower behind Toussaint's military triumphs, they were in a good position to insist. And anyway, Toussaint had written a new constitution for the island in which he proclaimed his loyalty to France but declared himself governor-general for life. For all these reasons, Napoléon decided to reconquer the island and restore slavery. He sent an army under his brother-in-law Charles Leclerc (1772–1802) in 1801.

THE FINAL STRUGGLE

Toussaint and some of his soldiers put up a stiff resistance, but ultimately the French troops, fresh from victories across Europe, triumphed. Toussaint himself was arrested and imprisoned in France, where he died in 1803. But disease began to take a toll on the French forces. At the same time, those Haitian soldiers who had surrendered when the French came began to realize that slavery was going to be restored. Toussaint's officers rose up in a new rebellion and fought a terrible struggle. More than a year of heavy fighting, marked by many massacres on both sides, resulted in the final defeat of the French forces at Vertières on November 18, 1803. The new commander of the Haitian forces, Jean-Jacques Dessalines (c. 1758–1806), tore the white out of the French flag, expelled or massacred the remaining white inhabitants, and declared Haitian independence on January 1, 1804. The cost of freedom will never be known, but the population of Haiti fell by at least 125,000 between 1789 and 1804.

AFTERMATH AND WIDER IMPLICATIONS

Haiti became independent in 1804, but no nation recognized it until the 1820s. Simón Bolívar (1783–1830) took refuge in Haiti during his struggle against Spain, but even the newly independent nations of the Americas did not want to have anything to do with a nation of freed slaves. Haiti was too potent an example to the blacks in the rest of the hemisphere. Haiti's leaders were demonized in French and American propaganda of the time and since, and Haiti was and to some extent still is held up as an example of how black people cannot rule themselves and need supervision. But black people were not so easily fooled. Haiti became a rallying cry for black liberation movements from Denmark Vesey's (c. 1767–1822) planned uprising in South Carolina in 1822 to Ahmed Sékou Touré's (1922–1984) call for the independence of the Republic of Guinea in Africa in 1957.

Haiti ceased to be a major producer of sugar or coffee after 1804, as most Haitians left the plantations and became peasants. Isolated from the world, Haiti preserved many elements of African culture, including a vibrant spiritual and artistic tradition. The pre-revolutionary free coloreds, many of them of mixed race, and the leaders of the military struggle became an urban commercial ruling class who lorded it over the mostly black peasants and affected a very European culture.

HALL, STUART

1932–

Stuart Hall, a black Jamaican born in 1932, was schooled—in the English manner—for a future as a member of the colonial elite. As he recounted on many occasions subsequently, he quickly discovered that he was living in two worlds simultaneously: as a black native of the Caribbean and on the other in the imaginative world of the colonizers, well attuned to the finest nuances in the history and the literature of the English. This discrepant sense of his place in the colonial world was at first puzzling and painful, but he learned over many years to make it his own. What once had been a burden came, through an intellectual journey of impressive imaginative power, to
become a resource and indeed a lifeline. This migrant's-eye view of the center from the margins informed every aspect of Hall's intellectual life. It underwrote, if only implicitly, the emergence in Great Britain of cultural studies, with which Hall himself became so closely identified. Later in life, this view explicitly defined his intellectual project.

Hall's early experience as a colonial subject produced a political radicalism that remained with him through his life. In 1951 he arrived in Britain as a student at Oxford University. He experienced England not only in its idealized manifestations, but also in its raw everydayness, in which the dispositions of racial exclusion loomed large. Later in the 1950s he was drawn to the emergent New Left, alongside the slightly older generation of Raymond Williams (1921–1988) and Edward Palmer Thompson (1924–1993). Crucial to the political critique that came from this moment was the realization that culture was not only the preserve of the educated elite, but that it was also properly the inheritance of all. To later generations this may sound a truism, but at the time it served to shift the study of culture away from a restricted meaning, in which culture represented only the most elevated, to a broader, more anthropological reading of the cultural dimensions of the everyday, in which the relations of a society are embedded in their symbolic conditions of existence. It served, too, to highlight the connections between political power and culture. From this point on, the characteristic tenor of Hall's interventions was to highlight his belief that the seemingly arcane practice of politics was in fact rooted in and fought out on the terrain of culture itself. More specifically, any politics of value needed to situate itself within the field of popular life, for it was there that political energies were generated and political causes won and lost.

Many of these ideas came together in the *Universities and Left Review*, with which Hall was associated, and then in its more famous successor, the *New Left Review*, which Hall edited for the first year of its existence, from 1960.

In 1964 Hall moved to the Centre for Contemporary Cultural Studies based at the University of Birmingham under the leadership of Richard Hoggart (b. 1918). Here he was given the space to develop conceptually the ideas that he—and those around him—had pursued in more practical form in early works such as his study *The Popular Arts* (1964), written with Paddy Whannel. Hall became the presiding figure in the emergence of cultural studies in the United Kingdom. His migrant perspective was an essential element in his reading of the culture of the British, and from this position the erstwhile colonial subject could offer his own anthropology of the erstwhile colonizer. The passions and excitement of early cultural studies ran deep. A vast range of previously excluded or derided cultural forms burst into view: popular music, advertising, women's magazines, youth fashion, movies, and television. All were taken as serious subjects for critical analysis and, collectively, as the site where (through many displacements) politics in its expanded sense occurred.

A decisive theoretical influence for Hall was the work of the Italian Marxist Antonio Gramsci (1891–1937). Gramsci's insistence on the place of culture as a constituent element in political struggle offered an analytical framework that served Hall well. The field of cultural studies, in its early incarnations, sought to unravel the many determinations by which political power was exercised. From this period in the 1960s, Hall collaborated with others to produce a mesmerizing stream of work, interpreting the emergent cultures of the time. His readings of youth subcultures and of the media comprehensively recast the field of the social sciences.

As this work evolved it met much resistance, not least because it was perceived as overly theoretical and as prone to an abstract formalism. Hall himself was certainly influenced by the work of the great structuralist theorists of culture—Ferdinand de Saussure (1857–1913), Claude Lévi-Strauss (b. 1908), Roland Barthes (1915–1980), and later Louis Althusser (1918–1990)—and was persuaded of the need to pitch his arguments, when the occasion demanded, at a high level of abstraction. But he also possessed a sharp sense of the movements of historical time. His analytical interpretations began from the chaos of the concrete realities of the everyday, and—although they often involved some theoretical detour—always returned to the concrete. Here especially the influence of Gramsci was profound. Often Hall described his own intellectual practice as one devoted to explaining the shifts and turns in the movement of political conjunctures.

This bid to bend formal structural analysis into a practice more alive to the movements of historical forces and cultural relations generated two classic essays in the early 1970s: his famous rumination on the workings of the mass media, “Encoding and Decoding in the Media Discourse” (1973), which set the conceptual frame of the emerging discipline of media studies for the next 30 years, and his more philosophically inspired (if modestly titled) “Marx's Notes on Method” (1974) in which, in explicating Marx, he outlined the basis of his own commitment to “theorising” the concrete.

It was during this period, too, that Hall and his colleagues embarked upon a comprehensive account of the drift in Britain toward a more authoritarian politics. Crucial to this analysis was his insistence that race—the management of the black population who, like him, had come to settle in Great Britain after the end of World War II (1939–1945), and of their sons and daughters—was a
Hallucinogens

central, defining feature of an increasingly conservative political reflex, in which recourse to authority dominated. His jointly authored volume, *Policing the Crisis* (1978), represented a landmark text, which in a bravura intellectual act brought into a single analytical frame the workings of high politics in Westminster with the emergent street politics of the new racialized ghettos.

Beginning in the late 1970s, Hall reworked and refined these early insights into a succession of inspirational articles that plotted the makings of Thatcherism, a term Hall employed even before Margaret Thatcher became prime minister in May 1979. Hall argued that Thatcherism represented a new form of authoritarian populism that marked a decisive shift to the right in British politics.

The drama of these writings was driven by a clear sense of political urgency created by the success of the Thatcherite project. At the same time, Hall also delivered broadsides to the political left, insisting that its characteristic inability to modernize or to think in terms of the future rather than the past was contributing to the confidence of the right. Many on the left took exception. At this point, too, Hall—having earlier been condemned for his formalism—found himself under attack for being too historical and not formal enough. His critics believed that the concepts that animated his discussion—authoritarian populism, crisis of hegemony, war of position, and so on (all derived from Gramsci)—were too inconsistent to be of use to social scientists. Hall’s response was simply to insist on the necessity of conjunctural analysis. Less contentious, however, was Hall’s early prediction that, whatever the fate of Thatcher herself, Thatcherism as a broader political project would define what was politically possible for many years to come, in which respect he provided a prescient perspective on the subsequent years of the New Labour government.

Race was still a major part of Hall’s intellectual concern, and beginning in the 1970s it became ever more prominent in his theorizations. From his study of race—of blackness—he became ever more preoccupied with questions of identity and subjectivity, especially of those on the racialized margins of the former colonizing nations.

An important interlocutor for Hall at this time was his student, Paul Gilroy, the author of *There Ain’t No Black in the Union Jack* (1987), which delivered a devastating critique of the racial encodings of the English nation. Gilroy learned much from Hall, though there remain significant political and intellectual differences between them, particularly in relation to their respective interpretations of the idea of black Britishness.

In 1997 Hall retired from his appointment as professor of sociology at the United Kingdom’s Open University, a position he had held since 1979. As his formal academic career came to an end, Hall moved into a new intellectual field: that of the visual arts. He believed it was here, among young black artists in the United Kingdom, that questions of race and identity were being addressed most fruitfully. As he came to discover, the artists he was interested in were, as he would say, “doing the theory for you.”

**HALLUCINOGENS**

The term *hallucinogen* refers to a variety of substances capable of inducing profound altered states of consciousness. Also known as *phantastica*, *psychedelics*, *entheogens*, and *psychointegrators*, these substances have a long history of use in societies throughout the world.

The “major” hallucinogens are LSD, mescaline, psilocybin (found in “magic mushrooms”), and the tryptamine derivatives (found in ayahuasca). These substances alter sensory perception and produce changes in a person’s...
body image and awareness of space and time, but they do not cloud consciousness and have little impact upon memory. Persons typically remain fully aware of the effects as they are occurring and retain vivid memories afterwards. Although the chemical structures of these substances vary and their mechanisms of action are not yet fully understood, dopamine, serotonin, and norepinephrine receptor sites have been implicated in their activity. While Cannabis ("marijuana") is sometimes included in this list, its effects and mechanism of action are distinct and involve other receptor sites.

The “minor” hallucinogens include anticholinergic substances (atropine and scopolamine) that block acetylcholine receptors. These produce relatively mild perceptual and cognitive changes, but they do cloud consciousness and impact memory, so that individuals may be unable to recall their experiences. The “psychedelic anesthetics” (ketamine and phencyclidine or PCP) affect NMDA receptors and induce profound dissociative effects.

The use of hallucinogens in traditional cultural settings has been extensively documented. These substances induce a hypersuggestible state that makes those who ingest them receptive to the messages received during initiation into adulthood and in religious rituals. Because the experiences are explained before they are induced, the effects are understood within a culturally defined and socially sanctioned framework that reassures the initiates and provides emphatic evidence of the “correctness” of the foundational premises of their society’s worldview.

Although traditional societies have been using hallucinogens for culturally constructive purposes for millennia, scientific interest in hallucinogens is comparatively recent. In the late 1800s, anthropological studies led to the recognition of the visionary effects of the peyote cactus. Subsequent research led to the isolation (1896) and synthesis (1919) of mescaline, the primary hallucinogenic component of peyote. Mescaline was thus the first hallucinogen to become available as a pharmaceutical preparation. The fantastic descriptions of the effects produced by mescaline attracted the attention of both scientists and artists, a pattern that would be repeated with other hallucinogens.

In 1938, Albert Hofmann, a Swiss chemist working at Sandoz Laboratories, first synthesized LSD (lysergic acid diethylamide) during his research into potential analgesics. During subsequent research in 1943, Hofmann accidentally ingested a miniscule amount of the drug (through the skin) and soon noticed marked perceptual changes and other effects. He then undertook a self-experiment using what he thought was an extremely small dose (250 micrograms) and experienced even more profound effects. Hofmann was later asked to identify the active constituents (psilocybin and psilocin) in samples of “magic mushrooms” (Psilocybe spp.) collected in Mexico. Uncertain of their usefulness and desiring to determine if there was a market for these substances, Sandoz made LSD (under the name Delysid) and psilocybin (known as Indocybin) available for psychiatric, therapeutic, and experimental research.

During the 1950s and early 1960s, considerable scientific research was conducted into hallucinogens. In clinical settings, these substances showed promise in treating chronic alcoholism, psychological trauma, pain, and obsessive-compulsive disorders. The U.S. and British governments also investigated the potential of hallucinogens as agents of chemical and psychological warfare. In the 1950s and 1960s, the CIA, in a project known as MKULTRA, gave scopolamine, mescaline, LSD, psilocybin, and other agents to numerous individuals, often without their knowledge. The unpredictability of the effects and the suicide of several subjects led to the termination of this work.

As knowledge about the visionary effects and therapeutic potential of the hallucinogens became more widespread, numerous artists, writers, and scientists had “psychedelic” experiences that profoundly affected their work. One of the first was Aldous Huxley (1894-1963), whose experiences with mescaline led him to write The Doors of Perception (1954) and Heaven and Hell (1956), two essays that introduced hallucinogens to the public. Another influential figure was the Harvard psychologist Timothy Leary (1920–1996), who first encountered psilocybin mushrooms during a trip to Mexico in 1960. Leary subsequently obtained a large quantity of psilocybin from Sandoz and began to offer it to other Harvard faculty and graduate students. With his team, he also administered psilocybin to violent criminals, with promising results.

Leary and others also investigated the effects of hallucinogens upon artists, musicians, and other creative individuals. As the circle of people who had had an experience with a hallucinogen expanded, increasing numbers of individuals became interested in these substances. Eventually, “acid tests,” “be-ins,” and other events provided the opportunity for thousands of people to simultaneously experience the effects of a hallucinogen. For many, the inner worlds revealed by these substances offered a stark contrast to consumerism, the push to conform, and the war in Vietnam. “Psychedelic” music, art, and poetry gave expression to these experiences, challenged conventional morality and authority, and led to the emergence of a “counterculture” that maintained that peace, love, and “flower power” could change human consciousness and alter the political landscape. In the late 1960s, governments reacted by enacting laws prohibiting the use, possession, manufacture, and distribution of most.
hallucinogens. While this did curtail some illicit use, it also put a stop to legitimate research.

Scientific research with human subjects resumed in the 1990s. In pilot studies, hallucinogens have been administered to terminal patients to help them confront their impending death, and they have been used to treat victims of post-traumatic stress disorder and sufferers of cluster headaches. The ancient tradition of hallucinogen use within a religious context is continued in the Native American Church, which uses peyote, and by several Brazilian churches (including the Santo Daime and União de Vegetal [UDV]) that use ayahuasca. These religious movements have achieved great success in helping their members overcome addictions to alcohol and other drugs, and they are legally allowed to use specific hallucinogens as “sacraments.”

In 1999, U.S. Customs agents seized a shipment of ayahuasca that had been shipped to the United States for use by an American chapter of União de Vegetal. The government claimed that the mixture contained substances banned by U.S. and international law. However, a 2006 U.S. Supreme Court decision unanimously affirmed that the government had not demonstrated a compelling interest in prohibiting the UDV from using ayahuasca in their religious services, thereby allowing them to use it legally in the United States.

Increased recognition that hallucinogens can be used for constructive purposes has led to renewed calls to review and, where appropriate, reduce the legal restrictions on these substances. In the United States, mescaline, LSD, psilocybin, psilocin, and even Cannabis are currently categorized as Schedule I substances, which are defined as having a high potential for abuse, a lack of acceptable safety when used under medical supervision, and a lack of currently accepted medical use. Similar restrictions exist internationally. However, these legal classifications are not consistent and are rarely adjusted as new scientific findings and patterns of illegal use become known. In many jurisdictions, drug classification often reflects political and social trends rather than scientific data. For example, in the United States the major hallucinogens are listed in Schedule I along with heroin, a substance that is available to physicians and patients in Europe. In contrast, methamphetamine, one of the most addictive and personally destructive drugs known, is classified as a Schedule II drug with a currently acceptable medical use. Moreover, many experts consider alcohol and tobacco to have a much greater potential for both personal and social harm than any of the hallucinogens (including Cannabis).

The 2003 National Survey on Drug Use & Health estimated that 34,363,000 Americans (14.5% of the population) had used a hallucinogen (excluding Cannabis) at least once in their lives. The same survey estimated that 96,611,000 persons (40.6%) had used Cannabis at least once. Worldwide, the United Nations Office on Drugs and Crime (UNODC) reported in 2006 that approximately 162,400,000 people used Cannabis in 2005 (3.9% of the total world population between the ages of 15 and 64). The UNODC did not report on the prevalence of LSD, peyote, or mescaline use.

In contrast to heroin and methamphetamine and the legal drugs ethyl alcohol and nicotine, hallucinogens (including Cannabis) are not physically addictive, and such substances as LSD, mescaline, and psilocybin even exhibit cross-tolerance with one another, meaning that daily dosages quickly lose their effectiveness. Both the traditional patterns of use and the increasing scientific evidence that many of the major hallucinogens can be useful in treating various disorders and in personal growth, and that Cannabis is an effective remedy for glaucoma, pain, the side effects of chemotherapy, and for many other purposes, demonstrates that a rethinking of drug laws in general, and the potential roles of hallucinogens in particular, is long overdue.

HAMILTON, ALEXANDER
1755–1804

When Alexander Hamilton was born on the small Caribbean island of Nevis, probably in 1755, he seemed destined for obscurity. His parents never married. When Hamilton was ten his father abandoned Hamilton and his mother and brother, and his mother died two years later. Strong natural abilities and the patronage of well-to-do citizens made possible Hamilton’s escape. He was sent to North America to receive a college education, which was cut short by the American Revolution. Hamilton took up arms on the American side. His abilities came to the attention of George Washington (1732–1799), who brought him into his personal staff. This began one of the most consequential partnerships in American history. Hamilton was always the junior partner, but the vigor of his character and intellect were critical for Washington’s success.

After the Revolution, Hamilton took up law as a profession and became active in local, state, and national politics. He served as member to the Continental Congress, agitated for a constitutional convention, and participated in the 1787 Constitutional Convention in Philadelphia. It was after the convention that Hamilton’s primary contributions to the new Republic began. Hamilton organized the writing of The Federalist Papers and contributed a little more than half the essays. He contributed mightily in the very difficult struggle to get the Constitution ratified in the critical state of New York. Washington, as the United States’ first president, appointed Hamilton his first secretary of the treasury, a role in which Hamilton distinguished himself as an original economic thinker and a model civil servant. He established the Treasury Department, dealt decisively with the nation’s financial crisis, put in place a financial system that remains in the early twenty-first century, and sketched out a plan and justification for the encouragement of manufactures. As treasury secretary, Hamilton also made a substantial contribution to the debates regarding the scope of the executive power and the proper way to interpret the Constitution.

Much was of enduring significance in Hamilton’s political and economic thought. Hamilton believed the task facing Americans was to show that, despite its historical record of failure, republican government was compatible with liberty and the public interest. In a speech at the Constitutional Convention on June 18, 1787, Hamilton advocated the inclusion of institutions, “as far … as republican principles will admit,” that would lend energy and stability to the republican form, which he defined as an equality of political rights—that is, a system without any hereditary political privileges (Hamilton 2001). At the Constitutional Convention, Hamilton proposed an elected president and senate to serve during good behavior. His suggestions about the presidency led to a charge of monarchism that followed him for the rest of his life. Although Hamilton favored a lower house that was democratic, he believed that republicanism’s best chance for success lay in establishing institutions that could check the popular spirit and pursue a steady course of administration.

The Constitution of course did not meet Hamilton’s expectations, but he threw his prodigious energies into the fight for its ratification. During this debate and while serving as secretary of the treasury, Hamilton elaborated an argument for energetic government in general and energy in the executive in particular. Hamilton may have been the first to employ the term energy in a political sense, using it to mean activity, vigor, and decisiveness in government. Energy is, he reasoned, more likely to arise when power is placed in one set or a very few sets of hands. Hamilton argued for a prompt and generally strict execution of the law. He considered it his job as treasury secretary to provide guidance for the legislative branch in its deliberations on economic matters. More generally, Hamilton provided the classic argument for a broad construction of the executive power under the Constitution. During the controversy over Washington’s declaration of neutrality between revolutionary France and its enemies, Hamilton argued that Article II granted the president the executive power as a whole, including what the English philosopher and economist John Locke (1632–1704) had termed the “federative power” over foreign affairs, subject to the exceptions explicitly spelled out in the Constitution. Hamilton’s position was consistent with his overall view that the Constitution should be construed liberally, or broadly, so that it might meet not just today’s needs but “the probable exigencies of ages,” as he put it in essay No. 34 of The Federalist Papers (Hamilton 2001, p. 311).

Joseph A. Schumpeter described Hamilton’s reports as treasury secretary as “applied economics” at its best” (Schumpeter 1954, p. 199). The reports contain both sophisticated economic theorizing and an extraordinary attention to the details of administration. To correct the nation’s financial crisis, Hamilton proposed a funding system that dedicated revenues to meeting the nation’s debts, new taxes, an assumption of the state debts accumulated during the American Revolution, and the establishment of an independently operated national bank that would be both the government’s banker and a facilitator of economic development. Believing that a capital shortage was the nation’s deepest economic problem, Hamilton attempted to modernize the financial system of the public and private sectors. He also proposed a plan to encourage manufacturing by providing government support for
essential defense industries and for infant industries. In
general, Hamilton supported free trade at home and
abroad, but he was willing to make exceptions to compensate
for the restrictions on trade established by other govern-
ments and to overcome the force of habit that attached
Americans to agricultural employments. In this regard,
Hamilton departed from the free-market prescriptions of
the Scottish economist Adam Smith (1723–1790). In
addition, unlike Thomas Jefferson (1743–1826) and
James Madison (1751–1836), Hamilton did not see any-
thing degrading or corrupting in manufacturing.

Hamilton struggled to find a political role for himself
after he resigned from the Treasury in January 1795. His
chief achievements of the period were the drafting of
Washington’s Farewell Address and his argument in the
Croswell case. In the 1804 Croswell case Hamilton argued
before the New York Supreme Court that truth ought to
be a defense in libel cases. Croswell had published claims
that while he was vice president, Jefferson had paid for
attacks on the characters of Washington and John Adams.
Hamilton lost the case, but his position soon became the
law in New York and in many other states. Other ventures
did not go as well. His interference with the cabinet of
the second U.S. president, John Adams (1735–1826), earned
him Adams’s intense hatred. His affair while treasury secre-
try with Maria Reynolds became the new Republic’s
first great sex scandal when it was revealed in 1797. When
recalled to serve as second in command of the army dur-
ing the “quasi-war,” the significant but undeclared naval
war with France (1798–1800), his ambitions for the army
led to suspicions that he harbored imperial ambitions for
himself.

Hamilton’s remarkable life came to an end in his duel
with Aaron Burr (1756–1836) in 1804. Hamilton had
been working to thwart Burr’s political ambitions for
more than a decade, but his work to defeat Burr’s guber-
natorial hopes that year was probably the last straw. The
challenge to a duel was an affair of honor that Hamilton
could not, as a man of the world, decline. Hamilton seems
to have decided to throw away his shot, but Burr shot to
kill, taking the life of one of the most consequential men
of the founding generation.

HAMILTON’S RULE

The dominant paradigm in economics holds that individu-
als in society seek to maximize their own self-interest. As
Adam Smith observed, however, even selfish individuals
have something in their nature that makes them altru-
istic. The British evolutionary biologist William D. Hamilton
(1936–2000) attempted to give this altruism a biological
basis. Hamilton expressed a rule for the evolution of social
behavior as \( rb - c > 0 \), where \( r \) is a measure of genetic relat-
edness between an actor and a recipient, \( b \) is benefits to a
recipient, and \( c \) is the cost to the actor of altruistic behavior.

The degree of genetic relatedness among kin follows a
decaying progression—from mother and child, to
mother and nephew or niece, and so on. The implication
of the progression is that closely related kin have a higher
measure of genetic relatedness. Indeed, the probability
that two relatives possess the same rare gene is high,
because of a phenomenon known as kin selection. Accord-
ing to Hamilton, one’s willingness to sacrifice for
others—whether individuals, a group, or society—can be
measured by the degree of kinship involved.

Hamilton’s rule has been used to study altruism,
aggression, and selfishness in social interaction. Genes
that have survived through Darwinian competition can be
deemed selfish and are responsible for the selfish behavior
in individuals known as individual selection. In Darwin’s
view of natural selection, the fittest survive. However,
individuals evolve to act for the good of the species or
society, through a process known as group selection. The
argument for group selection is that a person who sacri-
fices for a group is more likely to survive than one who
sacrifices for selfish benefits.

Individual and group selections can be profitably ana-
lyzed using the tools of game theory. If a woman is able to
select the sex of a child, she will choose the sex that will maximize the welfare of her grandchildren. Gaming enters the process because the outcome of her decision will depend on the sex ratio in the population, which is a consequence of what other females selected as the sex of their child. Building on Hamilton's and others' works, John Maynard Smith has derived an evolutionary stable strategy (ESS) for such games. An ESS can be achieved by each woman tossing a coin to make her selection, yielding a 50:50 chance of selecting a male or a female. With today's technology, a person can now know the sex of a child before birth, but if abortion or other changes relating to wars, customs, and politics occur, then no ESS is guaranteed.

Some applications of Hamilton's rule to economics have been successful. In a 2005 study, Samuel Bowles and Dori Posel examined migrant workers who remit income to their families. If a migrant with wage $w$ transfers an amount, $t$, to his or her family with pre-remittance income, $y$, then the marginal cost to the migrant is $1/(w - t)$, and the marginal benefit to the recipient is $r/(y + t/n)$. Optimal transfer occurs when the marginal benefit equals the marginal cost.

Some aspects of the Hamilton rule appear anomalous. Hamilton assumes that parents invest equally in male and female children, whereas economists usually think of parents as investing up to the point where equality of marginal benefits and costs occurs—and thus generally investing more in male children. More generally, the idea that genetic selection guides economic behavior seems somewhat problematic: Genetic changes are slow, whereas changes in prices, advertising, and R&D have an immediate effect.

HAPPINESS

The economics of happiness is an approach to assessing welfare that combines the techniques typically used by economists with those more commonly used by psychologists.

While psychologists have long used surveys of reported well-being to study happiness, economists only recently ventured into this arena. Early economists and philosophers, ranging from Aristotle (384–322 BCE) to Adam Smith (1723–1790), Jeremy Bentham (1748–1832), and John Stuart Mill (1806–1873), incorporated the pursuit of happiness in their work. Yet, as economics grew more rigorous and quantitative, more parsimonious definitions of welfare took hold. Utility was then taken to depend only on income as mediated by individual choices or preferences within a rational individual's budget constraint.

The study of happiness or subjective well-being is part of a more general move in economics that challenges these narrow assumptions. The introduction of bounded rationality and the establishment of behavioral economics opened new lines of research. Happiness economics—which represents one new direction—relies on more expansive notions of utility and welfare, including interdependent utility functions, procedural utility, and the interaction between rational and nonrational influences.

Richard Easterlin was the first modern economist to revisit the concept of happiness, beginning in the early 1970s. More generalized interest took hold in the late 1990s (see, among others, Easterlin 1974, 2003; Blanchflower and Oswald 2004; Clark and Oswald 1994;
The approach does not purport to replace income-based measures of welfare but instead to complement them with broader measures. These measures are based on the results of large-scale surveys, across countries and over time, of hundreds of thousands of individuals. The surveys provide information about the importance of a range of factors that affect well-being, including income but also others, such as health, marital and employment status, and civic trust.

The approach, which relies on expressed preferences rather than on revealed choices, is particularly well suited to answering questions in areas where a revealed-preferences approach provides limited information. Indeed, it often uncovers discrepancies between expressed and revealed preferences. Revealed preferences cannot fully gauge the welfare effects of particular policies or institutional arrangements that individuals are powerless to change. Examples of these include the welfare effects of inequality, environmental degradation, and macroeconomic policies. Amartya Sen’s (1995) capabilities-based approach to poverty, for example, highlights the lack of capacity of the poor to make choices or to take certain actions. Another area where a choice approach is limited is the welfare effects of addictive behaviors such as smoking and drug abuse.

Happiness surveys are based on questions in which the individual is asked, “Generally speaking, how happy are you with your life?” or “How satisfied are you with your life?” with possible answers on a four- to seven-point scale. The answers to happiness and life satisfaction questions correlate closely—ranging between .56 and .50 (Blanchflower and Oswald 2004; Graham and Pettinato 2002).

This approach presents several methodological challenges (Bertrand and Mullainathan 2001; Frey and Stutzer 2002b). To minimize order bias, happiness questions must be placed at the beginning of surveys. As with all economic measurements, the answer of any specific individual may be biased by idiosyncratic, unobserved events. Bias in answers to happiness surveys can also result from unobserved personality traits and correlated measurement errors (which can be corrected via individual fixed effects if and when panel data are available).

Despite the potential pitfalls, cross sections of large samples across countries and over time find remarkably consistent patterns in the determinants of happiness. Many errors are uncorrelated with the observed variables, and do not systematically bias the results. Psychologists also find validation in the way that people answer these surveys based in physiological measures of happiness, such as the number of “genuine”—Duchenne—smiles (Diener and Seligman 2004).

Microeconometric happiness equations have the standard form: \( W_{it} = \alpha + \beta x_{it} + \varepsilon_{it} \) where \( W \) is the reported well-being of individual \( i \) at time \( t \), \( X \) is a vector of known variables including sociodemographic and socioeconomic characteristics. Unobserved characteristics and measurement errors are captured in the error term. Because the answers to happiness surveys are ordinal rather than cardinal, they are best analyzed via ordered logit or probit equations. These regressions typically yield lower R-squares than economists are used to, reflecting the extent to which emotions and other components of true well-being are driving the results, as opposed to the variables that we are able to measure, such as income, education, and marital and employment status.

The availability of panel data in some instances, as well as advances in econometric techniques, are increasingly allowing for sounder analysis (van Praag and Ferrer-i-Carbonell 2004). The coefficients produced from ordered probit or logistic regressions are remarkably similar to those from OLS regressions based on the same equations. While it is impossible to measure the precise effects of independent variables on true well-being, happiness researchers have used the OLS coefficients as a basis for assigning relative weights to them. They can estimate how much income a typical individual in the United States or Britain would need to produce the same change in stated happiness that comes from the well-being loss resulting from, for example, divorce ($100,000) or job loss ($60,000) (Blanchflower and Oswald 2004).

THE EASTERLIN PARADOX

In his original study, Richard Easterlin revealed a paradox that sparked interest in the topic but is as yet unresolved. While most happiness studies find that within countries wealthier people are, on average, happier than poor ones, studies across countries and over time find very little, if any, relationship between increases in per capita income and average happiness levels. On average, wealthier countries (as a group) are happier than poor ones (as a group); happiness seems to rise with income up to a point, but not beyond it. Yet even among the less happy, poorer countries, there is not a clear relationship between average income and average happiness levels, suggesting that many other factors—including cultural traits—are at play (see Figure 1).

Within countries, income matters to happiness (Oswald 1997; Diener et al. 2003). Deprivation and abject poverty in particular are very bad for happiness. Yet after basic needs are met, other factors such as rising aspirations, relative income differences, and the security of gains become increasingly important in addition to.
income. James Duesenberry (1949) noted the impact of changing aspirations on income satisfaction and its potential effects on consumption and savings rates. A number of happiness studies have since confirmed the effects of rising aspirations, and their potential role in driving excessive consumption and other perverse economic behaviors (Frank 1999).

A common interpretation of the Easterlin paradox is that humans are on a “hedonic treadmill”: aspirations increase along with income and, after basic needs are met, relative levels of income matter to well-being. Psychologists’ “set point” theory of happiness, in which every individual is presumed to have a happiness level that he or she goes back to over time, even after major events such as winning the lottery or getting divorced (Easterlin 2003), provides a complementary interpretation.

Individuals are remarkably adaptable and in the end can get used to most things, and in particular to income gains (Kahneman et al. 1999). Easterlin argues that individuals adapt more in the pecuniary arena than in the nonpecuniary arena. Yet, because most policy is based on pecuniary factors, measures of well-being underestimate the effects of non-income factors, such as health, family, and stable employment.

There is no consensus about which interpretation is most accurate. Yet numerous studies demonstrate that happiness levels can change significantly in response to a variety of factors. Even under the rubric of set point theory, happiness levels can fall significantly in the aftermath of events like illness or unemployment. Even if levels eventually adapt upward to a longer-term equilibrium, mitigating or preventing the unhappiness and disruption that individuals experience for months, or even years, in the interim certainly seems a worthwhile objective for policy.

SELECTED APPLICATIONS OF HAPPINESS ECONOMICS

Happiness research has been applied to a range of issues. These include the relationship between income and happiness, the relationship between inequality and poverty, the effects of macropolicies on individual welfare, and the
effects of public policies aimed at controlling addictive substances.

Some studies have attempted to separate the effects of income from those of other endogenous factors, such as satisfaction in the workplace. Studies of unexpected lottery gains find that these isolated gains have positive effects on happiness, although it is not clear that they are of a lasting nature (Gardner and Oswald 2001). Other studies have explored the reverse direction of causality, and find that people with higher happiness levels tend to perform better in the labor market and to earn more income (Diener et al. 2003; Graham, Eggers, and Sukhtankar 2004).

A related question is how income inequality affects individual welfare. Most studies of OECD (Organization for Economic Cooperation and Development) countries find that inequality has modest or insignificant effects on happiness. The mixed results may reflect the fact that inequality can be a signal of future opportunity and mobility as much as it can be a sign of injustice (Alesina et al. 2004). In contrast, recent research on Latin America finds that inequality is negative for the well-being of the poor and positive for the rich. In a region with high inequality and weak public institutions and labor markets, inequality signals persistent disadvantage or advantage rather than future opportunity (Graham and Felton 2005).

Happiness surveys also facilitate the measurement of the effects of non-income components of inequality, such as race, gender, and status, all of which seem to be highly significant (Graham and Felton 2005). Relative social standing, meanwhile, has significant effects on health outcomes (Marmot 2004).

Happiness research can deepen our understanding of poverty. The set point theory suggests that a destitute peasant can be very happy. While this contradicts a standard finding in the literature—namely, that poor people are less happy than wealthier people within countries—it is suggestive of the role that low expectations play in explaining persistent poverty in some cases.

Perceptions of poverty vary. People who are high up the income ladder can identify themselves as poor, while many of those who are below the objective poverty line do not, because of different expectations (Rojas 2004). In addition, the well-being of those who have escaped poverty is often undermined by insecurity, and their reported well-being is often lower than that of the poor (Graham and Pettinato 2002).

Most studies find that inflation and unemployment have negative effects on happiness. The effects of unemployment are stronger than those of inflation, and hold above and beyond those of forgone income (Di Tella et al. 2001). The standard “misery index,” which assigns equal weight to inflation and unemployment, may be underestimating the effects of the latter (Frey and Stutzer 2002b).

Political arrangements also matter. Both trust and freedom have positive effects on happiness (Helliwell 2003; Layard 2005). Research based on voting across cantons in Switzerland finds that there are positive effects from participating in direct democracy (Frey and Stutzer 2002b). Research in Latin America finds a strong positive correlation between happiness and preference for democracy (Graham and Sukhtankar 2004).

Happiness surveys can also be utilized to gauge the welfare effects of various public policies. How does a tax on addictive substances, such as tobacco and alcohol, for example, affect well-being? A recent study on cigarette taxes suggests that the negative financial effects may be outweighed by positive self-control effects (Gruber and Mullainathan 2002).

**POLICY IMPLICATIONS**

Richard Layard (2005) makes a bold statement about the potential of happiness research to improve people’s lives directly via changes in public policy. He highlights the extent to which people’s happiness is affected by status—resulting in a rat race approach to work and to income gains, which in the end reduces well-being. He also notes the strong positive role of security in the workplace and in the home, and of the quality of social relationships and trust. He identifies direct implications for fiscal and labor market policy—in the form of taxation on excessive income gains and via reevaluating the merits of performance-based pay.

While not all agree with Layard’s specific recommendations, there is nascent consensus that happiness surveys can serve as an important complementary tool for public policy. Scholars such as Ed Diener and Martin Seligman (2004) and Daniel Kahneman and his colleagues (2004) advocate the creation of national well-being accounts to complement income accounts.

Still, a sound note of caution is necessary in directly applying the findings of happiness research to policy, both because of the potential biases in survey data and because of the difficulties associated with analyzing this kind of data in the absence of controls for unobservable personality traits. In addition, happiness surveys at times yield anomalous results that provide novel insights into human psychology—such as adaptation and coping during economic crises—but do not translate into viable policy recommendations. One example is the finding that unemployed respondents are happier (or less unhappy) in contexts with higher unemployment rates. The positive effect that reduced stigma has on the well-being of the unemployed outweighs the negative effects of a lower probability of future employment (Clark and Oswald...
One interpretation of these results for policy—raising unemployment rates—would obviously be a mistake. At the same time, the research suggests a new focus on the effects of stigma on the welfare of the unemployed. Happiness economics also opens a field of research questions that still need to be addressed, including the implications of well-being findings for national indicators and economic growth patterns; the effects of happiness on behavior such as work effort, consumption, and investment; and the effects on political behavior.

**BIBLIOGRAPHY**

**Carol Graham**
HARASSMENT

Harassment, which exists in many forms with different names, is most basically offensive behavior directed at a person, place, or entity. Most frequently, the target or victim of harassment defines or names the particular form of offensive behavior. Among the more common types of harassment are racial profiling, bullying, sexual harassment, hate crimes, and hazing. Regardless of the demographic or other characteristic of the victim, the goal of the harassment is to intimidate, exert power, or impose control over a victim.

The distinction between harassment and other forms of aggressive communication that are legal is based on societal and community standards. In societies that devalue free speech and open communication—in particular, disagreement with the government or other official personnel—harassment is often very broadly defined as written or verbal communications that are not sanctioned by an official governing body or that express open disagreement with the government.

In contrast, in societies where free speech is encouraged, harassment is typically defined as speech or communication that does not meet normal standards of accuracy or appropriateness, and is directed at a target who perceives the communication as disturbing, disruptive of occupational, educational, or interpersonal functioning, or injurious to reputation, position, or authority. That is to say, when brief and not overly frequent communications express concerns that validly correspond to errors or issues, then harassment is typically not present. Conversely, the greater the duration and frequency of communications and the smaller the validity of the claim, the greater is the likelihood that harassment is present.

These relatively complex definitions highlight the difficulty of identifying what meets the legal definition of harassment. For example, a communication that is perceived as harassment by its receiver may not have been sent for that purpose. Similarly, lengthy, frequent, but accurate communications directed at a person, place, or entity (as with political criticism) may or may not rise to the legal threshold of harassment. Nonetheless, despite these conceptual difficulties, the essential definition of harassment remains valid: It is an unwelcomed and unwanted verbal or nonverbal communication that produces an adverse consequence or negatively affects the emotional, cognitive, or behavioral functioning of one or more victims.

Sexual harassment in the workplace is a form of unwelcomed communication familiar to many individuals in the United States. Victims are frequently expected to accept harassment without complaint in exchange for promotions, raises, or continued employment. The Equal Employment Opportunity Commission defines sexual harassment as unwelcome sexual advances, requests for sexual favors, and other verbal or physical conduct of a sexual nature that explicitly or implicitly affects an individual’s employment, unreasonably interferes with an individual’s work performance, or creates an intimidating, hostile, or offensive work environment. Victimization by workplace harassment has been correlated with greater inefficiency, lowered productivity, and higher rates of absences.

Racial harassment is also a common form of unwelcome and harmful communication. Victims of ethnic or racial harassment, a specific form of racism, can experience negative health outcomes, including high blood pressure, elevated hostility, and frequent somatic complaints. Researchers have found that individuals experiencing racial or ethnic harassment are twice as likely to be daily tobacco users than those with no reported harassment experiences (Bennett et al 2005). Adjusting for age, harassed individuals are 70 percent more likely to report daily tobacco use in the past thirty days. It is beginning to be recognized that racial and ethnic harassment may be an important factor in explaining tobacco use among young African Americans. Those who perceive greater racial/ethnic harassment may also be at greater risk for affective disturbance and pathological cardiovascular reactivity (Bennett et al 2003; Merritt et al 2006). Continuous harassment can lead to persisting complications, including excessive self-blame, lowered mood, reexperience of the unwelcomed event, and generally increased anxiety.

Some forms of harassment are more socially acceptable than others. Because sexual harassment and hate crimes are illegal, there is an implied social agreement that these behaviors are wrong. In other instances, such as harassment of the obese, guidelines for acceptable behavior are much less clear and the prevalence of unwelcomed communications, both subtle and overt, is thought to be high.

Less recognized forms of harassment are also present. For example, a recent content analysis of prime-time television found that depictions of explicit and implicit sexual harassment of women are frequent (Grauerholz and King 1997). Incidents involving quid-pro-quo harassment were numerous. More than 80 percent of television shows in prime time contained at least one incident of sexual harassment not labeled as such.

Recently, behavioral scientists have begun to examine the effectiveness of training programs used to enhance the listening and helping skills of sexual harassment contact persons in the workplace (see Blaxall, Parsonson, and Robertson 1993). The majority of these studies have found that teaching designated and appropriate individuals in the workplace to respond appropriately to complaints of harassment, to recognize harassment’s warning
signs, and to respond empathetically to victims and firmly but fairly to perpetrators can help decrease sexual harassment and reduce its long-term consequences. Despite these encouraging indications, the most important mechanisms for the management of harassment inside and outside of the workplace appear to be laws, rules, regulations, and education.

Hard-core Unemployed

HISTORY
Policymakers, economists, and historians have long been interested in the problem of chronic joblessness. Much of this interest has corresponded to periods of market failures, like the Great Depression of the 1930s, when huge swaths of working-age persons were unable to find gainful work due to the collapse in aggregate demand.

However, policymakers, civil-rights leaders, and social critics noted a different, though related, phenomenon beginning in the 1960s. Significant numbers of persons were experiencing chronic unemployment even in economic “good times,” that is, periods of solid overall growth and low national unemployment. Moreover, there was a set of identifiable characteristics among these jobless persons.

First, they were generally disconnected from the labor market. Though some worked intermittently, they experienced long spells of joblessness that lasted anywhere from six months to numerous years. Second, they tended to have lower levels of education, at most a high-school diploma. Third, they were disproportionately, though by no means exclusively, minority. Fourth, in part due to their lack of employment, they were often poor or near-poor urban residents, and typically received some form of government assistance. Finally, some members of this group were alleged to have physical or mental handicaps; more recently, a criminal history has also been associated with long-term joblessness.

In his fifth State of the Union address (1968), President Lyndon Johnson (1908–1973) used the term hard-core unemployed, referring to approximately 500,000 Americans with these characteristics. Johnson also dubbed them the “last in line … the hardest to reach.”

THEORIES AND EXPLANATIONS FOR THE EXISTENCE OF STRUCTURAL UNEMPLOYMENT
There are three somewhat competing theories for the existence of chronic unemployment: these theories are based on productivity/skills mismatch and cultural explanations.

The first theory maintains that some persons, though willing to sell their labor at the going wage, simply lack the productivity to justify even the lowest wage on offer. Employers thus have no motivation to hire such persons, since their contribution to the firm’s output will be less than their pay, making them a net cost to the employer. As discussed below, policymakers motivated by this reasoning created tax credits to lower the labor cost to the employers associated with such hires.

The second theory stresses structural barriers: forces beyond the control of the individual that preclude him or

Christopher L. Edwards
Andrea Reeves

HARD-CORE UNEMPLOYED

The term hard-core unemployed was popularized in the late 1960s to refer to persons facing multiple barriers that appeared to block them from active, consistent participation in the job market. The term has largely fallen out of favor, though the concept—now termed structural unemployment—still has utility in today’s policy debates, particularly regarding economic disadvantages related to race.
Hard-core Unemployed

her from active participation in the job market. These barriers include racism; exclusion from opportunities available to the majority, such as a decent education; and economic changes that have reduced job opportunities to non-college-educated workers and those in particular geographical areas. In this explanation, the chronically unemployed have the necessary skills and attitudes to maintain a lasting connection to the job market. But forces outside their control, such as employers’ aversion to hiring minorities or the disappearance of jobs for which they are qualified, leave them without work for extended periods.

The third theory stresses personal shortcomings having more to do with attitudes, habits, and personal preferences than with skill limitations. The argument here is that the chronically unemployed have failed to internalize the dominant work ethic common among the majority. The result is that they devalue work in the paid job market, preferring outside sources of support, such as government assistance or the black market.

Of course, these theories overlap, and subsequent research has revealed that no single theory suitably explains the phenomenon. Relative to the other two theories, attitudinal explanations have less salience, as events and research have revealed that skill enhancement, policy interventions, and periods of strong labor demand have at times proven to diminish long-term joblessness among disadvantaged workers. That said, the problem is still very much with us.

POLICY DEVELOPMENTS AND THEIR IMPACT ON OUR UNDERSTANDING OF THE PROBLEM

The explanations discussed above, particularly the first two, led to various policy interventions designed to break the cycle of chronic joblessness in the United States. Presidents since Johnson have introduced and extended policy sets of training initiatives and tax credits to raise the skills of the hard-core unemployed and to lower their labor costs to employers (under such a credit, the government will pay some portion of the wage of workers who meet certain criteria).

Most of these programs remain in place today. The Targeted Jobs Tax Credit introduced in 1978, an employer-side credit of the type just noted, became the Work Opportunity Tax Credit in 1996. Numerous training programs for the least advantaged also remain in place under the rubric of the 1998 Workforce Investment Act. The welfare reform legislation of the mid-1990s also extended some of these programs.

The evidence of their effectiveness is mixed. The research on employer-side tax credits shows that while these programs sometimes have their intended effect, they are just as often used as an unnecessary windfall to employers who would have hired the same workers in the absence of the subsidy. Worker training programs also have a checkered history in terms of their effectiveness in offsetting the skill mismatch, but more recent, localized initiatives have shown greater success.

To some extent, the full employment period of the latter 1990s proved to be a potent antidote to structural unemployment, suggesting that depressed labor demand has been one factor responsible for chronic joblessness. During this period, the employment rates of many populations that had formerly been left behind grew sharply. Public policy interventions, including a higher minimum wage, an expanded Earned Income Tax Credit (an employee-side wage subsidy for low-wage workers in low-income families), and a set of work supports associated with welfare reform (e.g., subsidized child care or health care for working families), also played a role.

But the pull of the strong labor market, characterized by the lowest overall unemployment rates in three decades, was likely the dominant force in play in these years, and the employment rates (the share of the population at work) increased significantly for many, though not all, disadvantaged groups. Even some of the most disconnected groups benefited. For example, young African American males without a high-school diploma experienced a gain in employment rates from 32 percent in 1995 to 38 percent in 2005. Of course, even with this six point gain, such a low rate of employment is indicative of the problem of structural unemployment, but the positive trend is still notable evidence of the importance of very tight job markets.

CONCLUSION

Though the term hard-core unemployed is rarely used in contemporary discussions, compelling evidence reveals that certain groups of persons still face high barriers between them and the employment opportunities they need to raise their living standards. Unemployment rates for African Americans are consistently twice that of whites; the employment rates of young workers with less education, particularly minorities, remain far below overall averages.

Even in 2000, when national unemployment was 4 percent, the employment rate for young, African-American, male, high-school dropouts was 38 percent, far below the national average of 64 percent. Other research has shown that over 70 percent of young men with these characteristics were jobless or incarcerated in the mid-2000s.

Numerous explanations for this damaging phenomenon have been articulated and explored by researchers and policymakers. The findings generally show that these
workers face both skill deficits that hurt their employment prospects and a set of structural barriers, including weak labor demand, discrimination, and the absence of sustainable jobs where they live. Public policy and positive macroeconomic trends have been shown to make a helpful difference in the lives of these workers, but steep barriers remain in place.

For example, as economic inequality has grown and public budgets have become ever more strained, investments in public education have often lagged, particularly in disadvantaged areas where they are needed most. Rising inequality and poverty rates that are less responsive to economic growth have also meant that too many poor and near-poor families are unable to provide the necessary opportunities and advantages for young children, and these early disadvantages have lasting, negative consequences. Correcting these inequities, in tandem with pursuing policies to chip away at the deficits and barriers facing the structurally unemployed will help to diminish their numbers and connect them to the growing economy.

HARLEM

“In the history of New York,” begins James Weldon Johnson’s authoritative 1930s history Black Manhattan, “the significance of the name Harlem has changed from Dutch to Irish to Jewish to Negro” (p. 3). Though Johnson’s historical vantage was the dawn of the twentieth century, his observation is an ideal start for locating a fluid, rather than fixed, meaning for Harlem. His words pinpoint for his contemporaries, as well as later generations, three aspects of Harlem—its meaning, its transitions, and its multiethnicity—suggesting that it be infinitely defined in a shifting matrix of politics, economy, and culture.

Nieuw Harlem, as it was named by early Dutch settlers, was a farming community in the mid-1600s. Through the seventeenth and eighteenth centuries, Harlem belonged to the descendants of Dutch, French, and English settlers who oversaw its transition from an isolated, poor, and rural village to an upper- and upper-middle-class residential suburb. By the 1840s and 1850s, as the land’s productivity declined, many estate owners sold off or abandoned their properties. Irish immigrants arrived in Harlem as squatters, establishing shantytowns as well as a territorial claim to street and neighborhood boundaries.

With the elevated train pushing farther north between 1878 and 1881, fashionable brownstones and exclusive apartments were built to house a genteel class. By the 1890s Harlem’s brownstone aristocracy lived alongside Irish and Italian immigrants who populated low-lying spaces, marshland, and peripheral areas filled with tenement housing. German immigrants, including German Jews, joined the wealthy native American and European immigrant population. Economic success in the late 1890s also pulled upwardly mobile Eastern European Jews out of the Lower East Side as they, too, became Harlemites. Harlem was even home to a “little Russia.”

In spite of its well-known reputation as the cultural capital of black America, Harlem had few black residents until a wave of white flight produced a remarkable transition at the beginning of the twentieth century. The “great subway proposition” to extend a streetcar line to Manhattan’s upper reaches spurred wild real-estate speculation in Harlem. A bust came in 1905, however, as speculators faced an uncertain completion date for the subway. To save themselves from financial ruin, landlords were willing to rent properties to blacks. As middlemen, black real estate agents such as Philip A. Payton Jr., founder of
the Afro American Realty Company, John E. Nail, and Henry C. Parker steered clients to Harlem. Whites at first resisted, though in the end, established (white) tenants and white realtors were unsuccessful against what they called a “negro invasion.” As Jervis Anderson, a cultural historian of the Harlem Renaissance era, noted: “As the community became predominantly black, the very word ‘Harlem’ seemed to lose its old meaning” (1981, p. 60).

From about 1905, then, the formation of black Harlem was located at the spatial intersection of race relations and the demographic transformation of urbanizing America. The community, which covers 3,829 acres, is surrounded on all sides by the East, Harlem, and Hudson Rivers; its official boundaries run south to north from 96th Street to 178th Street in upper Manhattan. From the start of the twentieth century, however, Harlem has existed beyond geography.

From a period that roughly spans 1919 to 1929, the cultural movement defining the neighborhood’s heyday took place: the Harlem Renaissance. Black artists and intellectuals participated jointly in the creation of a new urban collective identity. As a center of urban black America, it was home to churches, hospitals, and other important social institutions that served a segregated community in Jim Crow America. The black “city within a city” exerted a magnetic pull as Harlem loomed large as a “symbol of liberty” and a “promised land.” As “queen of the blackbelts,” Harlem was a mecca for black activists, intellectuals, painters, and musicians. Its prominent writers included Langston Hughes, Claude McKay, Nella Larsen, and Zora Neale Hurston. Harlem was a stage, too, for important political spokespersons such as W. E. B. Du Bois and Marcus Garvey, who used Harlem as a platform from which to challenge racist America.

Those were the years, wrote Langston Hughes, when “Harlem was in vogue” (Hughes 1986, p. 227). For white downtowners a variety of Harlem’s clubs offered a glimpse and a thrill beyond the color line. Establishments such as Connie’s Inn, the Nest, Small’s Paradise, the Capitol, the Cotton Club, the Green Cat, the Sugar Cane Club, Happy Rhones, the Hoofers Club, and the Little Savoy staged music and dance numbers and, skirting the ban of prohibition, offered booze to white “slummers” and curiosity seekers. Ironically, some of the clubs had a Jim Crow policy that allowed black performers but excluded blacks as customers.

No consensus holds about the precise end of the Harlem Renaissance. The 1929 American stock market crash and the onset of the Great Depression, coupled with the end of Prohibition in 1933, loosely mark a transition to post-Renaissance Harlem. By the time of the 1935 Harlem Riot the luster was off. In a 1948 essay titled “Harlem Is Nowhere,” Ralph Ellison equated Harlem with madness, and argued that for “over four hundred thousand Americans … overcrowded and exploited politically and economically, Harlem is the scene and symbol of the Negro’s perpetual alienation in the land of his birth” (p. 296). From the 1930s to the 1960s, Harlem’s declining social conditions gave the neighborhood a sensationalist and decidedly negative reputation.

In the late 1960s and early 1970s urban renewal turned up on Harlem’s doorstep promising a turnaround. Within the community these slum clearance policies were derisively tagged “Negro removal.” This time Harlem’s transition became a struggle over whether redevelopment and reinvestment could coexist alongside preservation of its black cultural heritage. When 1980s noises of gentrification sounded through postindustrial urban America, they could be heard knocking at Harlem’s door. With the establishment of the Upper Manhattan Empowerment Zone in the mid-1990s, an era of public and private investment was initiated in Harlem to offset years of decline and disinvestment. By 2000 Starbucks had arrived in Harlem, touching off complicated questions about who belongs in Harlem and to whom Harlem belongs. As far back as 1930, James Weldon Johnson had presciently asked: “Will the Negroes of Harlem be able to hold it?” (p. 158). At the dawn of the twenty-first century, gentrification offers a window into the past, present, and unknown future definition(s) of Harlem.

HARLEM RENAISSANCE

The Harlem Renaissance (c. 1918–1935) was a blossoming of African American creative arts associated with the larger New Negro movement, a multifaceted phenomenon that helped set the directions African American writers and artists would pursue throughout the twentieth century. The social foundations of the movement
included the Great Migration of African Americans from rural to urban spaces and from South to North, dramatically rising levels of literacy, and the development of national organizations dedicated to pressing African American civil rights (the NAACP), “uplifting” the race and opening up socioeconomic opportunities (the National Urban League), and developing race pride, including Pan-African sensibilities and programs (the United Negro Improvement Association and the Pan-African conferences). Black exiles and expatriates from the Caribbean and Africa crossed paths in metropoles like New York and Paris following World War I (1914–1918) and had an invigorating influence on each other that gave the broader “Negro renaissance” (as it was then known) a profoundly important international cast.

The term Harlem Renaissance, which became popular in later years, particularly after the term Negro lost currency, derives from the fact that Harlem served as a symbolic capital of the cultural awakening, a dynamic crucible of cultural cross-fertilization, and a highly popular nightlife destination. Harlem was a relatively new black neighborhood becoming virtually a black city just north of Central Park, and it attracted a remarkable concentration of intellect and talent. More “liberal” in matters of race than most American cities (although, of course, racism was rampant), New York had an extraordinarily diverse and decentered black social world in which no one group could monopolize cultural authority, making it a particularly fertile place for cultural experimentation. Moreover, being situated in New York—the publishing capital of the Western Hemisphere, one of the world’s great ports, and the financial as well as cultural capital of the United States—put Harlem in a strategic position for developing black arts and sending them out to the world. Few of the well-known black writers or artists were born in Harlem, but almost all of them passed through it, were inspired by it, or achieved their reputations in part because of what happened there.

The Harlem Renaissance took place at a time when European and white American writers and artists were particularly interested in African American artistic production, in part because of their interest in the “primitive.” Modernist primitivism was a multifaceted phenomenon partly inspired by Freudian psychology, but it tended to extol so-called “primitive” peoples as enjoying a more direct and authentic relationship to the natural world and to simple human feeling than so-called “over-civilized” whites. They therefore were presumed by some to hold the key to the rennovation of the arts. Early in the twentieth century, European avant-garde artists including Pablo Picasso (1881–1974) had been inspired in part by African masks to break from earlier representational styles toward abstraction in painting and sculpture. The prestige of these revolutionary experiments caused African American intellectuals to look on African artistic traditions with new appreciation and to imagine new forms of self-representation, a desire reinforced by rising interest in black history. Black History Month, now Black History Month, was first celebrated in 1926 at the instigation of the historian Carter G. Woodson (1875–1950).

The interest in black heritage coincided with a general interest, among American intellectuals and artists generally, in defining an “American” culture distinct from that of Europe and characterized by ethnic pluralism as well as a democratic ethos. Thus the concept of cultural pluralism inspired notions of the United States as the first “transnational” nation, in which diverse heritages should develop side-by-side in harmony rather than be “melted” together or ranked on a scale of evolving “civilization.” W. E. B. Du Bois (1868–1963), the dominant black intellectual of the day, had already advocated something like this position in his famous book, The Souls of Black Folk (1903), a defining text of the New Negro movement because of its profound effect on an entire generation that formed the core of the Harlem Renaissance.

According to Du Bois and his colleague at the NAACP, James Weldon Johnson (1871–1938), the only uniquely “American” expressive traditions in the United States had been developed by African Americans because they, more than any other group, had been forced to remake themselves in the New World, while whites continued to look to Europe, or sacrificed artistic values to commercial ones. The very oppression that African Americans had suffered had made them the prophets and artistic vanguard of “American” culture. This judgment was reinforced by the immense popularity of African American music, especially jazz, worldwide. The popularity of jazz among whites was shaped in part by interest in the “primitive and exotic” and helped spark a “Negro Vogue” in cities like New York and Paris in the mid to late 1920s. Simultaneously, European dramatists extolled the body language of African American dance and stage humor (descended from blackface minstrelsy, America’s most popular and original form of theatrical comedy). The most well-known white man to bring attention to the “Harlem” Renaissance was undoubtedly Carl Van Vechten (1880–1964), whose music criticism extolled jazz and blues and whose provocatively titled novel Nigger Heaven (1926) helped spread the Negro Vogue, serving virtually as a tourist guide to Harlem and capitalizing on the supposed “exotic” aspects of black urban life, even while focusing, primarily, on the frustrations of black urban professionals and aspiring writers. Vilified by many but defended by the likes of Langston Hughes (1902–1967), James Weldon Johnson, and Nella Larsen (1893–1963), Van Vechten became a key contact for several black artists and authors because of his interracial parties and publishing connections.
In addition to primitivism, the tendencies to press for “authentic” American art forms, and to find them in black America, led black writers to “the folk” at a time when American anthropologists led by Franz Boas (1858–1942) were revolutionizing their discipline with arguments against the racist paradigms of the past. The “folk”—people of the rural South particularly, but also the new migrants to northern cities—were presumed to carry the seeds of black artistic development with relative autonomy from “white” traditions. Thus James Weldon Johnson, in God’s Trombones (1927), set traditional African American sermons in free-verse poetic forms modeled on the techniques of black preachers. Jean Toomer (1894–1967) was inspired by southern folk songs and jazz to lyrical modifications of prose form. Most famously, Langston Hughes turned to the blues for a poetic form derived from and answering to the desires, needs, and aesthetic sensibilities of the black working class. Sterling Brown (1901–1989) followed Hughes in a similar spirit with ballads and other poetic forms, attempting to catch the spirit of the folk heritage without merely imitating “folk” performance.

The Jamaican-born author and radical socialist Claude McKay (1889–1948) produced “proletarian” novels extolling the primitive authenticity and vitality of the black working class in Home to Harlem (1928) and Banjo (1929), a Pan-Africanist novel set in Marseilles, France. More influentially, Zora Neale Hurston (1891–1960)—an anthropologist and folklorist partly trained by Franz Boas—developed a new language and approach to narrative fiction inspired by black “folk” expressive traditions, most famously and successfully in her novel Their Eyes Were Watching God (1937).

In a completely different register, Nella Larsen explored the psychology of urban sophisticates in her novels Quicksand (1928) and Passing (1929), analyzing the psychological intricacies of race consciousness, and exposing the massive pressures to subordinate women's sexuality to the rules of “race” and class. The daughter of a white immigrant from Denmark and a black West Indian cook, Larsen knew intimately the price that color-line culture exacted of those who transgressed its most fundamental rules, and her fiction remains unequalled for the originality and incisiveness with which it exposes the contradictions of identities founded on the assertion of absolute difference between “black” and “white.” Hers was a unique achievement at a time when de facto and de jure segregation were becoming ever more entrenched features of American society.

By the mid-1930s, the optimism of the “renaissance” was wearing thin as the Great Depression clamped down and Marxist orientations (never absent from the renaissance) gained dominance. Black writers—above all, Langston Hughes, who had emerged as one of the stars of the “renaissance” and began working in numerous genres—began defining their new directions in contrast to the renaissance of the 1920s, describing the work of the earlier decade as too “racialist” in orientation (as opposed to Marxist and class-conscious) and as too dependent on wealthy white “patrons.” The characterization was reductive, as most such attempts at generational self-definition tend to be. Today it is clear that the Harlem Renaissance marked a turning point in black cultural history and helped establish the authority of black artists over the representation of black culture and experience, while creating a semiautonomous aesthetic field in the realm of “high culture” that has continuously expanded.

**HARRIS, ABRAM L., JR. 1899–1963**

Abram Lincoln Harris Jr., an African American scholar and activist, was born in 1899 in Richmond, Virginia, and finished his undergraduate work in 1922 at Virginia State University, a historically black college in Petersburg, Virginia, near his hometown. He completed an MA in economics at the University of Pittsburgh in 1924, and received his PhD in political economy at Columbia University in 1930. Harris served as a faculty member and chair of the Department of Economics at Howard University, the capstone of black higher education, in Washington, D.C., from 1927 to 1945 and subsequently served on the faculty of the University of Chicago until his death in 1963.

Harris was the first African American PhD in economics who pursued a rigorous academic career, publishing fifty works, including two seminal books and important essays in leading economics journals, such as the *Journal of Political Economy* and the *American
Economic Review. He also wrote extensively for public intellectual and activist journals, including Opportunity, the Crisis, the Nation, and the New Republic. His early scholarly books and articles focused on the economic conditions of African Americans and the best strategy to ameliorate these conditions. These studies reflected a decidedly activist and Marxian inclination. His later work retreated from concrete strategies of social reform and focused instead on the doctrines of economic reform in the writings of Karl Marx (1818–1883), Thorstein Veblen (1857–1929), and John Stuart Mill (1806–1873).

During his early professional years in the 1930s, Harris played a pivotal role in the critical and contentious debate over the best strategy for black progress in the United States. He decried the strategy of “black capitalism” as unrealistic (Harris 1936) and advocated instead the formation of a national multiracial working-class party to bring about social reform (Spero and Harris 1931). Leading the “Young Turks” of the Second Amenia Conference in 1933, and with W. E. B. Du Bois (1868–1963) looking on with general favor, he proposed that the U.S. African American leadership change course from its focus on civil rights (i.e., legal and political reform organized around individual cases) and undertake instead a more radical, class-based, mass approach to social reform. The following year, at the request of the NAACP’s board chair Joel Spingarn (1875–1939), Harris assembled the Committee on the Future Plan and Program of the NAACP, which proposed a breathtaking reform of the organization that, if implemented, would have transformed it into a politically active workers’ university with local chapters serving as branch campuses. This reform would have immered the NAACP in labor advocacy and education, laying the intellectual basis for black-white labor action on immediate issues, including pensions, unemployment insurance, child and female labor, lynching, public discrimination, and Jim Crow (Holloway 2002, pp. 93–100).

The radical Abram Harris of the 1930s rejected interracial conciliation of the Booker T. Washington (1856–1915) variety, the civil libertarianism of Walter White (1893–1955), and the militant race-consciousness of Marcus Garvey (1887–1940). He opposed the more nuanced version of race consciousness advanced by Du Bois, who argued (Du Bois 1940, chap. 7) for a period of self-segregation by African Americans, during which time they would form consumer and producer collectives to create a strong social foundation that would allow them to ultimately unify with white workers (currently blinded by racial prejudice) in establishing a socialist United States. Du Bois advocated this position as early as May 1933 in his address to the Conference on the Economic Status of the Negro sponsored by the Rosenwald Fund (Lewis 2000, p. 311). Harris rejected this strategy while fully recognizing the extraordinary challenge of bridging the racial chasm in the labor movement (Spero and Harris 1931).

Harris left Howard University and joined the faculty at the University of Chicago in 1945, a transition that marked (but did not initiate) a dramatic change in his worldview and intellectual focus. Leaving behind both his sympathy for Marx and his focus on social reform to achieve black progress, he adopted the moderate socialism of John Stuart Mill. Mill’s philosophy accepts the individualist assumptions about human nature and society, assumptions that Harris had earlier skewed in defending the class perspective of Marx (Harris 1935). His rejection of Marxian tenets (Harris 1950) coincided with his withdrawal from engagement in the struggle for black progress. Enhancing human capital through better education and a stronger home life, he came to believe, would allow his black brethren to succeed in the marketplace. This point of view largely accepts the false promise that the market will, in a competitive process, reward firms that recognize talent regardless of race; the problem of racial inequity thus has a labor supply-side solution (Harris 1964). The solution to the race problem lay in improving black character and skills, a familiar theme sounded by today’s conservatives who oppose positive legal and economic action that might compensate for the legacy of slavery, sharecropping, Jim Crow laws and practices, and contemporary racial discrimination.

At Chicago, Harris remained close to his lifelong friend Frank Knight (1885–1972), the renowned conservative economist, and even found common ground with archconservative Milton Friedman (1912–2006) (Broder 2006; Darity 1989). Students at the University of Chicago considered Harris one of their best teachers, and he won the Quantrell Prize for Excellence in Undergraduate Teaching in 1961. Chicago posthumously honored Harris’s contributions to undergraduate education by naming a series of scholarship awards in his honor in 1976. Harris’s work remains seminal in the debate on the strategic way forward for black progress, ironically occupying important positions on dramatically opposite sides of the debate.

HARRIS-TODARO MODEL

In the 1960s the government of newly independent Kenya faced a difficult situation: Unemployment in Nairobi and other major cities was high and apparently rising. To cope with this problem, Tripartite Agreements were reached in which private-sector and public-sector employers agreed to increase employment in exchange for unions agreeing to hold wages at their current levels. The larger number of jobs was expected to reduce unemployment. However, in the event, urban unemployment appeared to have increased following the Tripartite Agreements rather than decreased, as far as anyone could tell.

In light of these events, John Harris and Michael Todaro formulated the Harris-Todaro model to explain the puzzle. At the core of the Harris-Todaro model were the following features. First, real wages (adjusted for cost-of-living differences) are higher in urban formal-sector jobs than in rural traditional-sector jobs. Second, to be hired for a formal-sector job, one has to be physically present in the urban areas where the formal-sector jobs are located. Third, and as a consequence of the first two features, more workers search for formal-sector jobs than are hired, employers hire some of the job seekers but not all of them, and those not hired end up unemployed. Fourth, for equality to be maintained between the expected wage associated with searching for an urban job and the expected wage associated with taking up a lower-paying rural job, the equilibrium arising in such a setting is characterized by urban unemployment. And fifth, any temporary difference in the expected wages between one sector and another is eroded as workers migrate from the low-expected-wage labor market to the high-expected-wage labor market.

The Harris-Todaro model produced two powerful policy results. The first concerns the policy of formal-sector job creation to employ the unemployed (who, in the Harris-Todaro model, are all in urban areas, because that is where the formal-sector jobs are assumed to be located). Such a policy, they concluded, would increase the formal-sector labor force by more than the number of new jobs created, thereby raising the number of urban unemployed. Thus, the solution to urban unemployment is not to create urban employment.

The second policy option that Harris and Todaro considered was a policy of rural development. If such a program could increase the rural traditional-sector wage, unemployment would then fall. Thus, in the Harris-Todaro model, the solution to urban unemployment is rural development.

Soon after the model was published, the government of Kenya followed the Harris-Todaro precepts by putting into place an integrated program of rural development. The result was that unemployment in Kenya fell.

Harris and Todaro’s fundamental contribution was building a model that fit the stylized facts of the labor market they were analyzing and that was based on sound micro foundations. The fact that the model remains part of the economist’s intellectual toolkit today is a tribute to its basic insight and enduring analytic power.

The original model has been both simplified for some purposes and expanded for others by later contributors, including Stiglitz, Bell, Khan, Anand and Joshi, Bourguignon, Corden and Findlay, and others (Fields
HARTZ, LOUIS
1918–1986

Louis Hartz, the distinguished American political philosopher and intellectual historian, was to some degree a one-book celebrity scholar. His notable The Liberal Tradition in America, published in 1955, offered an original and influential interpretation of the American liberal paradigm that has remained at the center of debates over liberalism ever since. It was this book alone that defined Hartz’s career.

Hartz was born in 1918 in Youngstown, Ohio, to Russian immigrant parents, and grew up in Omaha. He spent most of his professional life at Harvard University. Hartz graduated from Harvard College in 1940 (supported in part by a scholarship from the Omaha World-Herald, as well as by a job waiting tables), and earned his PhD from Harvard in 1946. Ten years later he was a professor in Harvard’s Department of Government and the celebrated author of The Liberal Tradition. His Harvard lectures on eighteenth and nineteenth century European thought, and on American political theory and historiography, were notable and influential.

Hartz’s doctoral dissertation on the political and economic doctrines behind constitutional and political thinking in Pennsylvania after the Revolution was published as Economic Policy and Democratic Thought: Pennsylvania, 1776–1860, and helped set the agenda for his thinking about American liberalism. His later work included a volume he edited called The Founding of New Societies (1964) and his lectures on European thought, edited by Paul Roazen and published in 1990 as The Necessity of Choice: Nineteenth Century European Political Theory. The collection of essays published in The Founding of New Societies used the American founding experience as a comparative template to examine other new constitutions in Canada, Australia, and elsewhere. It also served to highlight Hartz’s own view of American liberalism as a unique manifestation rooted in a special history.

The core work in Hartz’s lifelong study of liberalism in its American and European settings, however, was The Liberal Tradition in America: An Interpretation of American Political Thought since the Revolution ([1955] 1991); everything he taught and wrote revolved around its arguments. The book won both the Woodrow Wilson Prize in 1956 and the Lippincott Prize (for a significant work still in print fifteen years after its publication) several decades later. Samuel Beer’s summary of the book’s thesis—“America’s democratic capitalism was so powerful that it excluded any ideas of socialism or Toryism”—only touched the surface of Hartz’s argument, which focused on what Hartz understood to be America’s defining narrative as a centrist society dominated by Locke’s liberal con-

sensualism. Locke might have appeared as a revolutionary figure and Enlightenment leader to France in the eighteenth century, as that country was deeply bound by feudalism. But in America, where landed property and feudal jurisdictions had never taken hold, Locke was a benign model of liberal consensus politics.

An historian as well as a theorist, Hartz embedded his argument about America’s putative centrist tendencies in the story of an exceptionalist country that, lacking a feudal past, was immune to socialist revolutionary appeals. In Hartz’s pithy words, “one of the central characteristics of a nonfeudal society is that it lacks a genuine revolutionary tradition, the tradition which in Europe has been linked with the Puritan and French revolutions…. And this being the case, it also lacks a tradition of reaction: lacking Robespierre it lacks Maistre, lacking Sydney it lacks Charles II” (1991, p. 5). No feudalism, no socialism; no traditionalism, no radicalism, and hence no reaction against radicalism. The result in the United States was a nation that never strayed too far from the center. Those individuals who did stray, whether Southern “feudalists” or modern socialists, exhibited in Hartz’s view a similar “fecklessness.”

Hartz used his analysis of liberalism in America to examine liberalism and revolution around the world. He worried less about the tyranny of the majority—a “puppy dog forever tethered to a lion’s leash”—than about whether people born equal could “ever understand peoples elsewhere that have to become so” (1991, p. 309). There is evidence enough today that they cannot.

Hartz became ill in the early 1970s and resigned from Harvard. His last years were tragic. He withdrew from family and friends and traveled the world with a kind of despondent urgency, stopping in London, Zurich, and New Delhi, and eventually reaching Turkey, where he died in 1986. A few years before his death he assembled extended but wildly uneven notes for a work to be called “A Synthesis of World History” (later privately printed as a typescript by Humanities Press in Zurich). This sprawling essay, an opus of Spenglerian ambitions, concludes with a turgid and frightening chapter on a Manichean “last battle” between Jihadists and pluralists. It envisioned an “explosion of fear” associated with a “drive for a single absolute” on the part of radical Islam and related movements, against which forces of diversity would be compelled to do battle—or witness the eclipse of civilization. Seen by many at the time as an expression of Hartz’s psychological problems, this final unfinished work today seems to exhibit a kind of perverse prescience, and reminds us that even after he had ceased to function as a scholar and teacher, Hartz continued to evince an ingenious mind informed by a brilliant if perfervid imagination. It was Hartz’s pedagogical and intellectual imagination that may explain why the author of a single great book written over a half century ago can continue to excite philosophers and historians into the new millennium.

HATE CRIMES

Although crimes against individuals based on their race, religion, ethnicity, and sexual orientation have a long and ignoble history throughout the world, the term hate crime was first popularized in the United States. In 1985 three members of the U.S. House of Representatives introduced legislation requiring the U.S. government to collect and publish statistical information on the growing number of bias-motivated crimes committed throughout the country. Enacted in April 1990, the Hate Crimes Statistics Act requires the U.S. Department of Justice to acquire and publish data from local law enforcement agencies on crimes that “manifest prejudice based on race, religion, sexual orientation or ethnicity.” The coverage was expanded to include disability in 1997. According to the
Federal Bureau of Investigation (FBI), “a hate crime, also known as a bias crime, is a criminal offense committed against a person, property, or society which is motivated, in whole or in part, by the offender’s bias against a race, religion, disability, sexual orientation, or ethnicity/national origin.”

The first FBI hate crimes report was published in 1993 and covered the calendar year 1991. Although this report, Hate Crime Statistics, is the official U.S. government tabulation of these crimes, some ethnic and other advocacy groups—including the National Asian Pacific American Legal Consortium and the National Coalition of Anti-Violence Programs, a gay rights organization—conduct their own annual audits of hate crimes. These groups claim that the FBI statistics underreport the number of hate crimes because victims are often afraid to contact law enforcement officials, fearing either stigmatization or the jeopardizing of their status as recent immigrants.

Prior to the passage of national hate crimes reporting legislation, the Anti-Defamation League (ADL)—the preeminent Jewish civil rights organization in the United States—drafted model hate crimes legislation in the early 1980s to punish criminal actions aimed at racial and other minority groups, including Jews. As of 2006, forty-six states and the District of Columbia have enacted legislation similar to the ADL model. These laws cover a wide variety of criminal activities, including vandalism directed at religious institutions and bias-motivated violence against individuals. Many states have enacted “penalty enhancement” statutes for hate crimes.

Some late twentieth-century bias-motivated crimes have received national attention. When a Hasidic Jewish driver accidentally ran over a seven-year-old African American boy in a Brooklyn, New York, neighborhood in 1991, an anti-Jewish riot ensued and local black youths murdered Yankel Rosenbaum, a visiting Australian scholar. On October 6, 1998, Matthew Shepard, a gay college student in Laramie, Wyoming, was savagely beaten because of his sexual orientation and later died. Earlier that year, James Byrd Jr., a forty-nine-year-old African American man was chained to a pickup truck in Jasper, Texas, and dragged to his death. His attackers were members of a white supremacist group.

Why should a hate crime be treated differently than any other criminal activity directed at individuals or property? What is the legal justification for enhancing the punishment for these crimes? These questions have persisted since the passage of the earliest hate crimes legislation and continue to provoke vigorous debate among legal scholars, legislators, and law enforcement officials. In his scholarly legal and philosophical defense of hate crime statutes, Punishing Hate, law professor Frederick M. Lawrence noted that:

Bias crimes spread fear and intimidation beyond the immediate victims to those who share only racial characteristics with the victims. Members of the target group suffer injuries similar to those felt by the direct victim of the actual crime. Bias crimes, therefore, cause a greater harm to a society’s collective living standard than do parallel crimes … and thus warrant enhanced criminal punishment. (Lawrence 1999, p. 63)

Legal scholars James B. Jacobs and Kimberly Potter, however, suggest that hate crime laws are unnecessary and create new crime categories that “may exacerbate rather than ameliorate social schisms and conflict” (1998, p. 144). Despite the continuing intellectual debate about the merits of hate crime statutes, the constitutional basis for these laws has been affirmed in the 1993 Supreme Court decision Wisconsin v. Mitchell. In addition, some state courts have upheld the legality of these laws.

Outside the United States, some European countries have enacted laws to criminalize hate crimes. The Vienna Declaration and Programme of Action, adopted in 1993 by the United Nations World Conference on Human Rights, calls on governments around the world to adopt measures “to counter intolerance and related violence based on religion or belief” and other practices directed against different minority groups. In 2005 Human Rights First—formerly the Lawyers Committee for Human Rights—conducted a study of the fifty-five members of the OSCE (Organization for Security and Cooperation in Europe) and found that nineteen of the fifty-five OSCE member states had enacted legislation declaring that racist motivation in crimes is to be “considered an aggravating circumstance in sentencing” (McClintock 2005, p. vii). Only five surveyed OSCE countries had hate crime statutes for bias-motivated crimes based on sexual orientation. Most third world countries do not have hate crimes legislation comparable to the West; some Muslim countries, in fact, prosecute homosexual behavior and there is occasional government-sanctioned or citizen-sponsored violence directed at gay men and lesbians.

HAUSMAN TESTS

Hausman tests (Hausman 1978) are tests for econometric model misspecification based on a comparison of two different estimators of the model parameters. The estimators compared should have the properties that (1) under the null hypothesis of correct model specification both estimators are consistent for the “true parameters” of the model (those corresponding to the data generating process), whereas (2) under misspecification (the alternative hypothesis) the estimators should have differing probability limits. The former property ensures that the size of the test can be controlled asymptotically, and the latter property gives the test its power. Heuristically, the key idea is that when the model is correctly specified, the compared estimators will be close to one another, but when the model is misspecified, the compared estimators will be far apart.

A Hausman statistic is constructed as a function of the difference between the two estimators. The sampling distribution of the Hausman statistic determines how big a difference is too big to be compatible with the null hypothesis of correct specification. One performs a Hausman test by comparing the Hausman statistic to a critical value obtained from its sampling distribution, and rejecting the null hypothesis of correct specification if the Hausman statistic exceeds its critical value. The large sample distribution of the Hausman statistic is straightforward to derive; a high-level analysis appears below. This distribution simplifies usefully when one of the compared estimators is efficient under the null, as originally proposed by Jerry Hausman (1978).

Two examples originally considered by Hausman help illustrate the ideas. First, consider estimating the coefficients of a single equation, say the first, of a system of linear simultaneous equations. Provided (among other things) that the system of equations is correctly specified, it is a standard result that both the two-stage least squares (2SLS) and the three-stage least squares (3SLS) estimators of the parameters of this equation are consistent. Further, under standard assumptions, the 3SLS estimator is asymptotically efficient; in particular, it is efficient relative to the 2SLS estimator. The difference between 2SLS and 3SLS will tend to be small in this situation. On the other hand, if one of the equations of the system is misspecified, then 3SLS is generally an inconsistent estimator for the parameters of every equation of the system. If the first equation is not misspecified, then 2SLS remains consistent. The difference between 2SLS and 3SLS may be large in this situation. Thus, by comparing the 2SLS and 3SLS estimators for one or more equations of a system of linear simultaneous equations, one can gain insight into the question of whether some equations of that system may be misspecified.

Another example treated by Hausman involves comparison of two different estimators for the parameters of a panel data regression model. Specifically, it is well known that both the “random effects” and the “fixed effects” panel estimators are consistent under the assumption that the model is correctly specified and that (among other things) the regressors are independent of the “individual-specific effects” (the “random effects” assumption). In this case, the random effects estimator is also asymptotically efficient. The difference between the random effects and the fixed effects estimators will thus tend to be small. On the other hand, if the random effects assumption fails but the model is otherwise correctly specified, then the fixed effects estimator remains consistent, but the random effects estimator is inconsistent. The difference between the random effects and the fixed effects estimators may therefore be large. A comparison of the random and fixed effects estimators can thus shed light on the correctness of the random effects assumption.

The first application of this approach appears to be that of James Durbin (1954), who proposed a test for “errors in variables” in a linear regression, based on a comparison of ordinary least squares (OLS) and instrumental variables (IV) estimators. Under correct specification (no errors in variables), OLS is consistent and efficient, whereas IV is consistent but inefficient. Under misspecification, OLS is inconsistent but IV remains consistent. De-Min Wu (1973) also considered tests based on a comparison of OLS and IV estimators, describing applications to linear simultaneous equations (OLS vs. 2SLS) and dynamic panel models. Alice Nakamura and Masao Nakamura (1981) discuss the relations among the test statistics of Durbin (1954), Wu (1973), and Hausman (1978).

Although Hausman’s initial motivation and examples concerned linear models and the orthogonality assumptions (e.g., independence) that are typically central to identification in econometric models, he particularly emphasizes the generality and unifying nature of the estimator comparison approach. Hausman’s formal results apply not just to linear models, but to maximum likelihood methods generally. As Halbert White (1994, chap.
10.3) discusses, Hausman’s approach further extends to quasi-maximum likelihood methods. This leads to useful specification tests based on two estimators such that (1) under partially correct specification both are consistent, but neither is necessarily efficient; and (2) under misspecification neither is necessarily consistent—it suffices merely that the estimators have differing probability limits.

Hausman’s unifying approach extends even more broadly. As a straightforward illustration, we give a result establishing the large-sample properties of the Hausman statistic based on a comparison of two asymptotically linear estimators. A wide variety of econometric estimators, including quasi-maximum likelihood, method of moments, and empirical likelihood estimators are asymptotically linear.

ASSUMPTION A.1 (ASYMPTOTIC LINEARITY)
Suppose each of two estimators, say \( \hat{\theta}_{1n} \) and \( \hat{\theta}_{2n} \), is a random \( q \times 1 \) vector such that for finite \( q \times 1 \) nonstochastic vectors \( \theta_j^* \), \( \hat{\theta}_{jn} \sim F_{\theta_j^*} \), \( j = 1, 2 \). Suppose further that for each \( j = 1, 2 \) there exists a \( q \times q \) nonstochastic matrix \( H_j^* \), finite and nonsingular, and a random \( q \times 1 \) vector \( s_{jn} = O_p(n^{-1/2}) \) such that

\[
\sqrt{n} (\hat{\theta}_{jn} - \theta_j^*) = H_j^*^{-1} \sqrt{n} s_{jn} + o_p(1).
\]

All limits here are taken as the sample size \( n \) tends to infinity. Our next assumption ensures the joint asymptotic normality of \( \sqrt{n} \hat{\theta}_{1n} \) and \( \sqrt{n} \hat{\theta}_{2n}^* \).

ASSUMPTION A.2 (JOINT ASYMPTOTIC NORMALITY)
For \( s_{jn}^* \) as in Assumption A.1, \( j = 1, 2 \), suppose that

\[
\sqrt{n}(s_{jn}^*, s_{jn}^*)' \rightsquigarrow N(0, J^*).
\]

where \( J^* \) is a finite \( 2q \times 2q \) nonstochastic matrix having \( q \times q \) diagonal blocks \( J_{11}^* \), \( J_{22}^* \), and \( q \times q \) off-diagonal blocks \( J_{12}^*, J_{21}^* = J_{12}^* \).

Hausman statistics are based on the difference \( \sqrt{n} (\hat{\theta}_{1n} - \hat{\theta}_{2n}) \). If Assumptions A.1 and A.2 hold and if, as can usually be arranged, the assumption of correct model specification ensures that \( \theta_1^* = \theta_2^* \), then it follows straightforwardly that

\[
\sqrt{n}(\hat{\theta}_{1n} - \theta_1^*) \rightsquigarrow N(0, V^*),
\]

where

\[
V^* = H_{11}^*^{-1} J_{11}^* H_{11}^{-1} - H_{11}^{-1} J_{11}^* H_{11}^{-1} - H_{11}^{-1} J_{12}^* H_{12}^{-1} + H_{11}^{-1} J_{22}^* H_{22}^{-1} - H_{12}^* H_{22}^{-1}.
\]

Under mild conditions, it is typically straightforward to obtain a covariance matrix estimator consistent for \( V^* \).

Let \( \bar{V} \) be such an estimator. If \( V^* \) is nonsingular, then an asymptotic chi-squared statistic is delivered by the analog of the Wald statistic,

\[
\nu((\hat{\theta}_{1n} - \hat{\theta}_{2n})' V^{-1}(\hat{\theta}_{1n} - \hat{\theta}_{2n}).
\]

Nevertheless, a common occurrence in applications is that \( V^* \) fails to be nonsingular, due to the singularity of \( J^* \). A straightforward remedy for this is to consider a subvector of \( \sqrt{n} (\hat{\theta}_{1n} - \hat{\theta}_{2n}) \) or, more generally, a linear combination \( \sqrt{n} S (\hat{\theta}_{1n} - \hat{\theta}_{2n}) \), where \( S \) is a known finite nonstochastic \( k \times q \) matrix, \( k \leq q \), such that \( S V^* S' \) is nonsingular. A Hausman statistic can then be computed as the quadratic form

\[
H_n = \nu((\hat{\theta}_{1n} - \hat{\theta}_{2n})' S' [S \bar{V} S']^{-1} S (\hat{\theta}_{1n} - \hat{\theta}_{2n}).
\]

In testing partially correct specification, \( S \) can also play a useful role by selecting or combining only those coefficients consistently estimated under partially correct specification.

We can now formally state the large-sample properties of this Hausman statistic.

PROPOSITION 1
Suppose Assumptions A.1 and A.2 hold and that \( S \) is a known finite nonstochastic \( k \times q \) matrix of full row rank. (i) If the model is correctly specified, and if correct model specification implies that \( S(\theta_1^* - \theta_2^*) = 0 \) and \( V_n \sim w^* \), where \( S V^* S' \) is nonsingular, then \( H_n \sim \chi^2_k \). (ii) If the model is misspecified, and if model misspecification implies that \( S(\theta_1^* - \theta_2^*) \neq 0 \) and \( V_n \sim w^* \), where \( W^* \) is a finite, nonstochastic \( q \times q \) matrix such that \( S W^* S' \) is nonsingular, then for any sequence \( \{c_n\} \), \( c_n = o(n^{-1}) \), \( P(H_n > c_n) \rightarrow 1 \).

The respective proofs of (i) and (ii) follow those of Theorems 8.6 and 8.16 of White (1994).

Part (i) establishes that under the null hypothesis of correct specification, the Hausman statistic is distributed asymptotically as chi-squared with \( k \) degrees of freedom (\( \chi^2_k \)), delivering convenient asymptotic critical values. Part (ii) describes the behavior of the Hausman statistic under the global alternative of model misspecification. This establishes the consistency of the test (power approaching one) for sequences of critical values going to infinity with \( n \) (but more slowly than \( n \)), thus driving the probability of Type I error to zero.

An important caveat for part (ii) is the necessity of the requirement that misspecification entails

\[
S(\theta_1^* - \theta_2^*) \neq 0.
\]

As Alberto Holly (1982) has pointed out, this can fail for particular types of misspecification in combination with particular choices of compared estimators. The
Hausman statistic just given is thus not guaranteed to yield a test consistent against arbitrary model misspecification. Nevertheless, a clever modification of the Hausman statistic proposed by Herman Bierens (1988) gives a variant of the Hausman test that does have this consistency property (see also Bierens 1990).

As mentioned above, the asymptotic distribution simplifies usefully when one of the compared estimators is efficient under correct specification. Specifically, the asymptotic covariance matrix of the estimator difference simplifies to the difference of the asymptotic covariance matrices. With asymptotic linearity, this arises because typically when one of the compared estimators (say $\hat{\theta}_{1w}$) is asymptotically efficient, then $f_{12} = H_2^*$ and $f_{12}^* = H_2^*$ (see Bates and White 1993). Substitution into the expression for $V^*$ above then gives the more convenient expression

$$V^* = H_{1w}^{-1} J_{1w} H_{1w}^{-1} - H_{2w}^{-1} J_{2w} H_{2w}^{-1}.$$

The first term is the asymptotic covariance matrix of $\hat{\theta}_{1w}$; the second term is that of $\hat{\theta}_{2w}$. A direct benefit of this expression is that it suggests simpler forms for the covariance estimator $\hat{V}_W$.

The specific form given above for the Hausman statistic is only one of several possible forms. Hausman describes a convenient version for linear regression applications that involves testing whether certain transformations of the original regressors have zero coefficients. Russell Davidson and James MacKinnon (1993) discuss further convenient versions of the Hausman test based on “double-length” regressions. Applying the results of White (1994, chap. 9) yields further variants of the Hausman statistic that have convenient computation properties.

The focus here has been on parametric versions of the Hausman test. The unifying principle of estimator comparison for specification testing also extends to comparing parametric and nonparametric estimators and to comparing nonparametric estimators. White and Yongmiao Hong (1999) give some relevant theory and examples for these cases.

HAYEK, FRIEDRICH AUGUST VON 1899–1992

F. A. Hayek, as he is known throughout the English-speaking world, is generally considered to be the leading twentieth-century representative of classical, nineteenth-century liberalism and the foremost scourge of socialism. Hayek was a corepipient, with Gunnar Myrdal (1898–1987), of the Nobel Prize in Economic Science in 1974, awarded “for their pioneering work in the theory of money and economic fluctuations and for their penetrating analysis of the interdependence of economic, social and institutional phenomena” (Nobel Foundation).

Hayek was born in Vienna on May 8, 1899, into a family of academic distinction on both parental sides. Having served in the Austrian army as an artillery officer on the Piave front during the latter stages of World War I (1914–1918), he entered the University of Vienna and earned doctorates in both law (1921) and political science (1923). In 1927 he became director of the newly established Austrian Institute for Business Cycle Research. In January 1931 Hayek delivered a series of lectures at the London School of Economics and Political Science, subsequently published as *Prices and Production*. As a result of these lectures, he was appointed Tooke Professor of
Economic Science and Statistics in the University of London later that year. In 1950 he joined the interdisciplinary Committee on Social Thought at the University of Chicago as professor of social and moral sciences. He returned to Europe in 1962 as professor of economic policy at the University of Freiburg, Germany. In 1969 he accepted a visiting professorship at the University of Salzburg in his native Austria. Hayek died in Freiburg on March 23, 1992.

Hayek was a strong believer in the supreme power of ideas. In 1947 he convened a group of like-minded scholars dedicated to classical liberalism to a meeting in Vevey, Switzerland, and thus the Mont Pelerin Society was born. From the mid-1970s Hayek was a pivotal figure in the renaissance of Austrian economics in the United States, and his ideas have exerted increasing political influence through think tanks such as the Institute of Economic Affairs in London and the Washington-based Cato Institute.

Hayek has made lasting contributions not only to economics but also to legal philosophy, theoretical psychology, social anthropology, political philosophy, the methodology of the social sciences, and the history of ideas. The polymathic range, far from suggesting a lack of focus, is indicative of a magnificent architecutural unity to his work. Steeped in the teachings of the Austrian school of economics derived from Carl Menger (1840–1921), Friedrich von Wieser (1851–1926), and Eugen Böhm von Bawerk (1851–1914), his early work on economic theory focused on marrying monetary theory, trade-cycle theory, and the theory of capital. His policy recommendation of “waiting it out” during the years of the Great Depression brought him into immediate conflict with Keynesian notions of underinvestment and underconsumption. As Sir John Hicks (1904–1989) pointed out in a retrospective assessment, Hayek’s model of the maladjusted time structure of production triggered by low interest rates is not so much a theory of fluctuation as a theory of growth. In this sense, Hayek’s theory of overinvestment was much more applicable to the situation of the long-lasting Japanese recession of the 1980s and 1990s or to the predicament in the United States in the late 1990s when interest rates were held too low relative to higher expected returns on capital, encouraging excessive investment, reduced savings, and the biggest stock-market bubble in U.S. history. Given Hayek’s objections to the possibility of measuring the money supply and of distinguishing sharply between money and other financial assets, it is full of irony to find him frequently dubbed “the father of monetarism.”

It was also during his London years that Hayek, elaborating on an argument of his mentor, Ludwig von Mises (1881–1973), attended to the issue of rational economic calculation in planning under centralist socialism. His misgivings about the latter as a viable economic system were closely linked to his views on how knowledge is generated and disseminated in markets and paved the way for his notion of competition as a discovery procedure in a world where tastes and production techniques are frequently changing and knowledge about these matters is dispersed. Market transactions draw on the scattered—among market participants—bits of practical, local knowledge, facilitating increasingly complex layers of specialization of labor without relying on any directing agency. The role of market prices, however imperfect as signals they may be, is to enable their users to adapt to events and circumstances about whose existence they may not have any clue whatsoever. The interactions of market participants using their own specific knowledge for their own projects generate a spontaneous order. The essential point about such a regular pattern of activities is that (1) it is emphatically not the result of design, neither by a single nor by a group mind, and that (2) its complexity puts insuperable limitations on control and prediction of the overall behavior of the system. In this sense, Hayek’s view of the workings of an economy is much more akin to biology than to mechanics.

Following in the footsteps of Scottish Enlightenment philosophers such as David Hume (1711–1776), Adam Smith (1723–1790), and Adam Ferguson (1723–1816), Hayek extended the notion of a spontaneously generated order to the evolution of social institutions such as law, language, and morals. The recognition of complex orders, and the nature of rules conducive to their formation and preservation, was the central enigma fueling Hayek’s intellectual ambition. It took him almost fifty years to grasp its full significance and to put it as succinctly as possible. This was a remote, painstaking academic pursuit constituting Hayek’s legacy as a scholar. But at the same time, he was a preacher possessed by an urge to save the world from collectivism.

HAYMARKET SQUARE RIOT

The Haymarket Square riot was a bloody confrontation between Chicago police and protesting workers. The state repression that followed in its wake left a permanent mark on U.S. and international politics. On May 4, 1886, a group of workers met in Haymarket Square in Chicago to protest an earlier police attack on workers that had left six people dead. The city had recently been the center of a bitter nationwide fight concerning the right of workers to an eight-hour workday.

Approximately three thousand workers turned out for the Haymarket protest. The mayor of Chicago, Carter Harrison (1825–1893), attended the meeting and informed police officials that the audience and the speakers were peaceful. The mayor and most of the workers left by 10:20 p.m., when a light rain set in. Only 500 workers remained when 180 Chicago policemen arrived to disband the meeting. A police official who had been in political conflict with the mayor ordered the immediate evacuation of the public square.

Just after the evacuation command was shouted, a dynamite bomb was thrown into the midst of the police. Whether the bomb was thrown by an agent provocateur or a worker has never been determined. The police responded with indiscriminate gunfire, killing both police officers and workers in the square. By morning almost all of the deaths in Haymarket Square had been blamed on labor leaders. This was the story reported by major newspapers, both locally and nationally, and it was the conclusion immediately reached by law enforcement officials.

Although there was no evidence linking them to the crime, eight prominent labor leaders and anarchists were arrested and tried for murder. The judge instructed the jury that evidence linking them to the deaths in Haymarket Square was not necessary for conviction. After a blatantly biased trial, seven of the men were found guilty and sentenced to death. Four men—Albert Parsons, August Spies, George Engel, and Adolph Fischer—were hanged on November 11, 1887, a date commemorated long after as Black Friday. The dominant media of the time portrayed the trial, the verdict, and the executions as triumphs of law and order.

The impact of the Haymarket Square riot, both on the labor movement and on American politics, was long-lasting. In the short term the Haymarket incident, after interpretation by the media, sparked America’s first red scare. Locally Chicago police banned public meetings and attacked labor leaders, anarchists, and socialists. The fact that four men had been executed for the public expression of controversial ideas had a negative effect on all of these groups. Nationally there was wider coordinated repression of such groups. Haymarket was blamed for destroying the Knights of Labor, then America’s largest and most inclusive labor union.

In the long run, however, the impact in the United States and internationally was more positive. The Haymarket narrative dramatized what came to be called “the Chicago idea,” which was that large labor unions could take concerted action to change economic, social, and political conditions. In addition the incident directly inspired the careers of future labor leaders, such as Bill Haywood (1869–1928) and Emma Goldman (1869–1940). The execution of the men, who became known as “the martyrs of Chicago,” not only inspired labor leaders globally but also led to the designation of May 1 as an international labor holiday. In short, the Haymarket massacre resonated long afterward as an enduring symbol of the heroic age of the labor movement.

HEAD START
Head Start began as an eight-week summer demonstration program in 1965, a small part of a larger antipoverty effort of the Lyndon B. Johnson (1908–1973) administration. The program was created to promote school readiness by enhancing the cognitive and social development of low-income children through provision, to such children and their families, of health, educational, nutritional, social, and other services that are determined, based on family needs assessment, to be necessary. Low-income children are those who come from families whose annual income falls below official poverty thresholds, although up to 10 percent of Head Start participants in local groups are allowed to come from families who do not meet the low-income criterion. Head Start is one of the few antipoverty measures that has enjoyed continued bipartisan political support in the U.S. Congress, and by 1975 what became known as the National Head Start Association was formally organized as an advocacy group for the program. Head Start operates full-day (six hours per day for four or five days per week year round) in about 50 percent of its local programs, with many service options. Although Head Start has served families with children three years of age and under in some programs since 1967, in 1995 the Early Head Start program awarded the first formal grants for birth-to-age-three services.

By the early 2000s Head Start had served about nineteen million children since its inception. In 1968 Head Start began funding a program that eventually was called Sesame Street, a Carnegie Corporation preschool television show. During its 2004 fiscal year Head Start enrolled nearly 906,000 children. Of these, 52 percent were four-year-olds, another 34 percent were three-year-olds, and another 9 percent were under three years of age; 31.2 percent were Hispanic, 31.1 percent were black, and 26.9 percent were white; and 12.7 percent had physical or mental disabilities. The average cost per child was $7,222, for a total cost of nearly $6.1 billion.

Although Head Start is a federal program, it is administered through the states and operated by local public and private for-profit and not-for-profit agencies. Hence, there is a great diversity of programs across the country and within states, thereby making difficult efforts to evaluate how well Head Start “works” in the nation as a whole. A national reporting system was created only in 2002, and the U.S. Department of Health and Human Services issued its first Head Start impact report in 2005. Data based on that reporting system indicate that Head Start children achieve a 38 percent gain in letter recognition and improved prewriting skills, but they still lag behind their more advanced peers at entry into kindergarten and such gains are likely to dissipate over time. One regional study reported in 2000 by Sherri Oden and others found that girls who attended Head Start in Florida in 1970 to 1971 were significantly more likely to graduate high school or earn a GED (95% versus 81%) and significantly less likely to be arrested at age twenty-two (5% versus 15%) than were girls in the non–Head Start comparison group.

Two studies by Janet Currie and Duncan Thomas relied on national-level data to examine the effects of Head Start participants. Their 1995 study showed that Head Start was associated with significant gains in test scores among both whites and African Americans, but that African Americans quickly lost those gains. Head Start also reduced the probability that whites would repeat a grade, but no such effect was found for African Americans. In their 2000 study, Currie and Thomas again reported that test scores “faded out” more quickly for black children than for white children, but they also showed that black children who attended Head Start were more likely to attend schools of worse quality than other black children. No such pattern was found for white children. These results suggested that the “fade out” effects for black Head Start children may be due to the inferior schools they attend.

A long-term study based on national-level survey data reported by Richard Caputo in 2003 indicated that Head Start children had the lowest income to poverty ratios between 1985 and 1998 (2.6 versus 3.3 for nonpreschoolers and 3.8 for other preschoolers). In regard to economic mobility between 1985 and 1998, both Head Starters and other preschoolers had statistically similar and greater upward mobility (0.67 and 0.51 deciles respectively) than did nonpreschoolers (0.16 deciles). These findings, however, should be interpreted cautiously given the lack of experimental controls. More rigorous studies with random assignment into experimental and control groups are
necessary to provide more definitive knowledge about both the short-term and long-term effects of Head Start.

HEAD START EXPERIMENTS

With growing concern about the number of children living in poverty in the United States, the Head Start program was initiated in 1965 as Project Head Start, one component in the “war on poverty.” Originally conceived as an eight-week summer pilot program implemented in nearly 2,500 communities across the country, the first trial served 500,000 four- and five-year-old children. From this initial beginning, Head Start programs quickly expanded to nine-month and even full-year programs, either half-day or full-day. As of 2006, the Head Start program served about 900,000 three- and four-year-old children nationally in nearly 19,000 centers for a total annual cost of $6.8 billion. Over time, the reach of the program has been substantial: Between 1965 and 2006, Head Start has enrolled more than twenty-four million children.

CHALLENGES OF PROGRAM EVALUATION

By providing a comprehensive set of education, health, and social services, Head Start aimed to counteract the detrimental influences of poverty and prepare children academically and socially for school entry. From its inception, there has been an interest in understanding whether Head Start indeed achieves this objective. However, a comparison of outcomes for children who participated in Head Start with those who did not would not measure the true effect of Head Start if program participants are systematically different from nonparticipants. For example, Head Start participants are on average from poorer families and they may come from families whose parents are more motivated to see their children succeed. These selectivity factors could confound efforts to measure the true effects of Head Start participation.

Ideally, we want to measure the effects of Head Start on children’s outcomes compared to what those outcomes would have been for the same children in the absence of the program. Since it is not possible to observe the same children both participating and not participating in the program, researchers turn to experimental and quasi-experimental methods to assess program effects. Well-designed and implemented randomized control trials—with study participants randomly assigned to participate in the program or remain in the control group—remain the gold standard among social science evaluation methods. Potential selectivity bias is eliminated because program participation is determined at random. A second-best alternative is the use of quasi-experimental methods using data on participants and nonparticipants where statistical methods are employed to minimize any selectivity bias.

The history of Head Start evaluations reveals many of the challenges associated with conducting systematic scientific evaluations of large-scale social programs. First, while a randomized control trial is the gold standard, implementation of such experiments may not be compatible with the objectives of delivering social services. For example, such experiments require resources that could alternatively be used for program delivery, and it is often considered unethical to withhold program services for a control group. Second, while much of the initial focus of Head Start supporters was on the potential short-term gains in IQ, other evidence indicated that the benefits of Head Start may be both broader and longer-lasting. In the context of experimental evaluations, this requires careful measurement of multiple outcomes and the ability to con-
duct a longitudinal evaluation that follows treatment and control-group children years or even decades into the future. Finally, Head Start is not one uniform national program. Rather, there is tremendous variation across program sites in the nature and delivery of program services. This variation means that evaluations of selected Head Start programs may not represent the effects on average for the country as a whole.

EARLY EVALUATION EFFORTS
Until the 1998 congressional reauthorization of Head Start, there was no nationally representative evaluation of the program using a randomized experimental design. Early evaluation efforts sometimes used experimental designs to study local area programs, or quasi-experimental designs to study larger, national samples of children who participated in Head Start and comparison children who did not. Results from this early body of research were potentially compromised by small sample sizes, high rates of attrition, nonrepresentative samples, and the selectivity of program participation. Such potential biases were also present in the seventy-six studies that were the focus of a meta-analysis of the literature known as the Head Start Evaluation, Synthesis, and Utilization Project (McKey et al. 1985).

Despite these limitations, the conclusion that emerged from this meta-analysis in the mid-1980s and the literature that preceded it was that Head Start could generate immediate cognitive benefits (e.g., higher IQ scores or achievement scores) for participating children, but those benefits did not persist after the first few years of elementary school as the gap between Head Start and non-Head Start children narrowed. There was some evidence that Head Start participants showed other improved outcomes over nonparticipants, such as lower rates of grade repetition and special education use, as well as physical health benefits. Similar findings had also been demonstrated for smaller-scale demonstration programs that offer one or two years of high-quality preschool education, although the magnitude of the effects for these smaller-scale and more resource-intensive programs were often larger than those measured for Head Start participants. More recent syntheses of this literature suggest that while the fade-out (relative to nonparticipants) of IQ gains from participation in Head Start or other high-quality early intervention programs may be real, the fade-out of achievement test scores may result from flaws in evaluation designs and follow-up procedures. This explanation can help reconcile the apparent achievement fade-out with the longer-lasting effects measured for such educational outcomes as grade repetition and special education use.

LATER EVALUATION EFFORTS
In the absence of large-scale experimental studies, researchers in the 1990s turned to nationally representative survey samples to estimate the short- and long-term benefits of participating in Head Start. Using rigorous quasi-experimental methods, these studies demonstrated that Head Start had favorable and more sustained effects on test scores and other school outcomes for white children, but the initial cognitive benefits for black children faded with time. For both white and black children, Head Start participation led to higher immunization rates but had no effect on nutritional status. Analysis of longer-term data also showed favorable effects of Head Start on high school completion, college attendance, and criminal activity, but again the benefits differed by race and ethnicity.

In the 1998 reauthorization of Head Start, Congress mandated a national study to measure the effects of Head Start on school readiness, broadly defined to include cognitive development, general knowledge, approaches to learning, social and emotional development, health status, and access to health care. The study also aims to evaluate the effects on parental practices that influence school readiness and the conditions under which the program is most effective and for which children. The evaluation underway randomly assigned about five thousand newly entering three- and four-year-old children applying for Head Start in nearly four hundred randomly selected Head Start centers to either participate in Head Start or be in a non-Head Start group (with access to non-Head Start programs in the community as selected by the parents). Findings from the first-year follow-up released in 2005 showed small to moderate gains for Head Start children in most of the domains listed above for entering three-year-olds, while fewer effects were found for the four-year-olds. The children in the study will continue to be followed through first grade, and possibly beyond, with an effort to identify overall program impacts as well as how the effects of Head Start vary with program characteristics or for different types of children.

Other demonstration projects implemented in the 1990s assessed other aspects of the Head Start program. One such evaluation—the National Head Start/Public School Early Childhood Transition Demonstration Study implemented from 1991 to 1998—was designed to test the effects of providing comprehensive transition supports (e.g., social services to strengthen families and links to school, services to increase parent involvement, and promotion of developmentally appropriate activities in the classroom curriculum) for Head Start children and their families, schools, and communities in kindergarten through third grade. The study design randomly assigned more than 450 schools in thirty-one sites to the treatment...
or control conditions, with more than eight thousand former Head Start children studied. While inferences that could be drawn about the effects of the transition supports were limited by the site-to-site variation in the treatment conditions and similar activities implemented in control schools, the study documented consistently large gains among former Head Start children (both treatment and control children) in reading and math achievement in these early grades, as well as substantial parent involvement in school and home activities.

**HEALTH ECONOMICS**

An enormous expansion in the scope and effectiveness of medical care services to diagnose and treat diseases began in the 1930s with the scientific research and development techniques that produced the first antibiotics. Those advances have been followed by continual changes in the organization of the institutions that constitute the supply and demand sides of the medical service industry, continual changes in pricing and payment mechanisms, and continual growth in the amount of nations’ resources that are allocated to medical services.

Theses changes have been universal among countries, even in the presence of substantial heterogeneity in institutional and market structures for health care delivery and financing. The United Kingdom and the United States are examples of nations with very different structures. In 1946 the United Kingdom established universal, government-funded medical insurance, and hospital and medical specialists’ services are produced by the government. In the United States, medical insurance is not universal; government expenditure is substantial, but provides coverage for only selected populations; physician practices are privately owned and organized on a for-profit basis; and most hospitals are privately owned but organized as non-profit-based corporations. Yet, between 1960 and 2004, total health care expenditure as a share of gross domestic profit doubled in the United Kingdom and tripled in the United States (Organisation for Economic Co-operation and Development 2007).

Health economics applies the tools of microeconomics to individual and societal decisions regarding the allocation and distribution of resources to the production of health and health care services. Kenneth Arrow’s 1963 article “Uncertainty and the Welfare Economics of Medical Care” established health economics as a field by making the case that virtually all of the special features of the medical care industry stem from the prevalence of risk and uncertainty, arguing that “the failure of the market to insure against uncertainties has created many social institutions in which the usual assumptions of the market are to some extent contradicted” (Arrow 1963, p. 946).

Demand- and supply-side analysis is the primary theoretical tool in health economics. On the demand side, health is characterized as a stock of human capital (Schultz 1961; Becker 1962) that produces both direct utility and investment services—capacity to function—over the life cycle. With aging it depreciates naturally and is increasingly subject to shocks from diseases. Replacement health cannot be purchased—it must be produced by combining personal resources such as time and health-affecting behaviors with purchased health or medical care services (Grossman 1972). On the supply side, purchased health care services are regulated by government and produced in hospitals, physicians’ offices, and clinics, and long-term care facilities by physicians, nurses, and other medical care providers using pharmaceutical and other diagnostic and treatment technologies.

The role of third-party payors—predominately employers and governments—constitutes a distinguishing feature of health economics. Given third-party payors, consumers often are not aware of the full range of alternative health care services and do not directly face, or even
know, the resource cost—the full price—of their health care. Most consumers are enrolled in managed care type plans that have contracts with providers. Those contracts influence providers’ treatment decisions by specifying which services are covered and what the payment mechanism is between the plan and medical services provider; the consumer does not see the plan-provider contract.

Health economics draws on tools used in several other fields to address this configuration of health and health care institutional characteristics: from public finance, the major government role; from labor economics, the major employer role; from industrial organization, restricted entry and nonprofit organizational form; and from econometrics, quantitative answers to policy-related questions. Variations of cost-effectiveness analysis are more frequently used by health economists in nations such as the United Kingdom, where government-financed third-party coverage is complete.

Much growth in the field of health economics is policy oriented. This can be attributed to the fact that governments are major third-party payors and face the fiscal implications of the costs associated with the expansion in the scope of medical care services. Thus, the research has focused on societal decisions regarding the efficient (cost-containing) allocation of resources to the production of health care services. Research concerning the distributional component of enhancing social welfare (Arrow 1963) has received much less attention in health economics. This has implications for policy because there is substantial evidence of nonrandom heterogeneity in health stock and health outcomes among demographic groups. Racial and ethnic health disparities continue to persist whether health care coverage is universal and provided by government, as in the United Kingdom (Townsend and Davidson 1982), or provided through fragmented systems of imperfect markets that include private and government third parties, as in the United States (U.S. Department of Health and Human Services 2000).

Viewed as human capital, investment in the health of the most vulnerable members of society may be a powerful tool for promoting growth. Public investment in programs that eliminate acquired immunodeficiency syndrome (HIV/AIDS) enhances social welfare and facilitates economic growth in developing African countries. Programs that increase breast-feeding enhance the health of infants and thereby generate positive long-term returns. But John Akin and colleagues reported that in Sri Lanka, highly educated mothers from families in the highest income or asset categories were among the least likely to breast-feed (Akin, Bilshower, Guelkey et al. 1981); thus the social rate of return from investment in health may be particularly high for developing countries, but the economic and policy issues are complex. Additional health economics studies can help clarify these issues.

HEALTH IN DEVELOPING COUNTRIES

The most commonly accepted definition of health was proposed by the World Health Organization (WHO) in its 1948 constitution: “Health is a state of complete physical, social, and mental well-being and not merely the absence of disease or infirmity.” Some academics argue that this definition is utopian, and they propose a more narrow definition that considers health to be “the absence of illness” (Alban and Christiansen 1995).

Health is regarded by the WHO as a fundamental human right. The preamble of the WHO constitution states that “the enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being.” However, people do not enjoy the same
standard of health in all parts of the world. Many factors influence health status and a country’s ability to provide quality health services for its people. Researchers on health in developing countries try to make sense of these factors and to understand their complex links in “low- and middle-income countries in which most people have a lower standard of living with access to fewer goods and services” (World Bank 2003).

Research on health in developing countries can include the study of clinical and epidemiological aspects of diseases, such as variations in disease frequency in different populations; the natural processes of biology and their relation to disease; the environmental and social determinants of health; and the development, implementation, and evaluation of health policy, which can include, among other things, how health systems should be organized.

The range of disciplines and professionals represented in the study of health in developing countries is very broad. This group can include epidemiologists, sociologists, physiologists, economists, mathematicians, historians, health policy analysts, nurses, doctors, and pharmacists. In recent years, there has been a move toward establishing research partnerships of interdisciplinary teams from both developed and developing countries in an effort to find solutions to the health challenges facing developing countries in the new millennium. The spectrum of diseases studied is wide, and there are major research groups working on topics that include reproductive health, undernutrition, and infectious disease (e.g., tuberculosis, malaria, diarrheal diseases, HIV/AIDS); noncommunicable disease and injury (e.g., diabetes, mental disorders, interpersonal violence); risk factors (e.g., water supply, sanitation, and hygiene); and the consequences of disease and injury (e.g., learning and developmental disabilities).

The global community acknowledges the need to tackle health-related conditions in order to support aspirations toward development of people living in developing countries. An example of this includes the United Nations Millennium Declaration (2000), signed by 189 countries, which includes eight Millennium Development Goals, three of which are related to health: reducing child mortality; improving maternal health; and combating HIV/AIDS, malaria, and other diseases (Travis et al. 2001). The following sections explore how some of these goals are being addressed.

HIV/AIDS poses a serious health, social, and economic threat worldwide, and both rapid action and drastic initiatives are needed to care for adults and children living with and affected by HIV/AIDS, as well as to prevent further infections from occurring. By 2004 AIDS had killed more than twenty million people, and an estimated thirty-four to forty-six million people were living with HIV/AIDS (WHO 2004). The solutions proposed by most experts include implementing a comprehensive HIV/AIDS strategy that links prevention, treatment, care, and support for people living with the virus. Providing effective antiretroviral treatment and new care strategies to strengthen existing prevention programs can result in the improvement of health, the reduction of HIV/AIDS stigma, and the rebuilding of social capital while restoring economic growth (WHO 2004).

According to the WHO’s World Health Report 2003, around 530,000 women die each year in pregnancy or childbirth, and 10.6 million children die every year before they reach the age of five. In many countries, universal access to health care for women and children is not assured. Women and children are often excluded from health-care services, which reinforces inequity in health delivery and increases barriers to progress. The WHO report also states that mortality could be reduced through a wider use of key interventions and a continuum of care for mother and child. Some cost-effective interventions include: expanding immunization coverage; treating diarrhea; preventing the transmission of and mortality from malaria; ensuring the widespread distribution of key micronutrients; improving prenatal and delivery care; and expanding the use of measures aimed at preventing mother-to-child transmission of HIV (Jamison et al. 2006). The most pressing task for reducing child mortality, improving maternal health, and treating and preventing HIV/AIDS consists of putting in place the health-care workforce needed to implement these interventions.

The effectiveness of health systems varies dramatically around the globe, even among countries with similar levels of income and health expenditure. In 2000 the WHO carried out the first analysis assessing the performance of health systems worldwide. The report emphasized that failures in health systems had a more severe impact on the poor. According to the report, out-of-pocket payments for health care exacerbate poverty. In light of this finding, governments should pursue policies that expand insurance and prepayment schemes as a way of reducing excessive out-of-pocket expenses for health care (WHO 2000; van Doorslaer et al. 2006).

International involvement in health care remains common in developing countries, largely because the provision of health care is expensive and few countries can afford universal coverage. International involvement includes the work of multilateral organizations such as the United Nations, bilateral or government-to-government organizations, and the global civil society. In addition, a wide range of global partnerships to finance the fight against major diseases in developing and middle-income countries have flourished since the mid-1990s.
Organizations participating in such partnerships include the Global Fund to Fight AIDS, Tuberculosis, and Malaria; the Bill and Melinda Gates Foundation; and the World Bank Multi-country HIV/AIDS Program. It is still too early to assess or predict the effects of these initiatives on health systems. The funds of such initiatives must be managed with caution, and they face daunting problems associated with coordinating their efforts within countries (Brugha 2004; Coovadia and Hadingham 2005).

In general, two approaches to delivering health interventions are prevalent. These approaches date back to a debate that started when the Alma-Ata Declaration was adopted at the International Conference on Primary Health Care in Alma-Ata (Almaty), Kazakhstan, in 1978. At that time, the debate centered on two distinctive views on primary health care (PHC) intervention. The first approach, referred to as selective PHC, focuses on diseases with the highest prevalence and morbidity, the highest risk of mortality, and the greatest possibility of control in terms of cost and effectiveness of the intervention (Walsh and Warren 1979). The second approach, named comprehensive PHC, considers health to be more than the absence of disease, and defines health in the holistic sense. Comprehensive PHC considers equity, multisectoral approaches, and community involvement as critical components of any health intervention (Rifkin and Walt 1986).

The debate between advocates of these two approaches has not completely faded, but it has been obscured by the fact that many governments and global health partnerships have implemented the selective PHC approach to tackle HIV/AIDS, as well as tuberculosis and malaria. However, the WHO's World Health Report 2003 stressed that the principles of the Alma-Ata Declaration remain valid, and should be reinterpreted in light of dramatic changes in the health field since 1978.

Health systems in developing countries need to be strengthened in view of the global health challenges facing them, including the health-care workforce crisis, a lack of financial resources, and poorly organized and financed health systems (WHO 2005). The World Health Report 2003 indicates that despite many reforms, inadequate progress has been made in building health systems that promote collective improvement in health. Solutions could include offering more training for local officials, strengthening health-care infrastructure through restructuring, and developing accountability mechanisms and a larger role for civil society. However, experts agree that context-specific strategies and responses are essential, and goals and priorities should be established and tailored to each country’s context (Sepulveda 2006). Finally, there is a need for greater research on epidemiology and health systems to improve the efficiency and reduce the costs of available interventions, as well as biomedical research to develop new tools for dealing with emerging health problems (Sepulveda 2006).

HEARSAY

In legal cases where the primary witness is a child, the courts face a dilemma: They must attempt to prosecute alleged criminals while also protecting child eyewitnesses. One way that the courts have attempted to deal with this dilemma has been to have a hearsay witness testify in place of the child eyewitness. In the U.S. legal system, hearsay is defined as “a statement, other than one made by the declarant while testifying at the trial or hearing, offered in evidence to prove the truth of the matter asserted” (Federal Rules of Evidence 801[c]). (The declarant is the witness of the original event).

Hearsay statements have not traditionally been allowed in the courts for several reasons. Not only is the veracity of hearsay testimony questionable, but hearsay testimony may also violate the defendant’s Sixth and Fourteenth Amendment rights to due process and to confront the accuser. However, there are still twenty-nine exceptions to the hearsay rule under the Federal Rules of Evidence, allowing hearsay testimony to be admissible in numerous instances.

The majority of these exceptions to the hearsay rule (twenty-three) are made when the declarant is available to testify. For these exceptions, the statement made by the declarant is seen as so reliable by the courts that the declarant does not have to testify. For example, these statements may relate to official written documents, or a statement may have been made for the purpose of medical treatment and therefore may be admissible under the medical diagnosis or treatment exception (Federal Rules of Evidence 803[4]). There are also several exceptions to the hearsay rule that are made only when the declarant is unavailable to testify. For example, if the declarant is not available to testify, then under the statement against interest exception (Federal Rules of Evidence 804[3]), a declarant’s prior statement may be admissible if it is self-incriminating. However, these statements are viewed by the courts as less reliable than the statements that are admissible when the declarant is present.

To accommodate cases where the declarant is a child who was allegedly abused, most states have special exceptions to the hearsay rule. The goal of such exceptions is to protect the child from the trauma of in-court testimony, while still providing the courts with a means of pursuing legal cases involving child victims. However, there are many problems with the use of hearsay testimony, including the inability of the prosecution to cross-examine the eyewitness and the fact that the declarant would not be under oath while making the original statement. Also, the jury will not be able to use the demeanor of the child as an aid in determining his or her accuracy. Finally, when a hearsay witness testifies in place of a child eyewitness or victim, there is the possibility that the hearsay witness either misunderstood the child or is fabricating the child’s statements, allowing further potential distortions in the declarant’s original statements.

Research evaluating the accuracy of hearsay testimony suggests that information is indeed lost when hearsay is used in place of the child’s testimony. Research indicates that while the interviewers of children tend to give complete and accurate reports of the gist of their interviews, this is not the case when interviewers are asked to report the types and content of the questions they asked children. Interviewers tend to report less than 50 percent of their own utterances made during the interview and 20 percent or less of the types of questions they asked children. Interviewers consistently report more free-recall prompts and fewer suggestive or leading prompts than were actually used, making the interview of the child appear to be more spontaneous than it really was. Therefore, jurors who are exposed to the testimony of a hearsay witness are likely to think that the child’s statements were more spontaneous than they were in reality, possibly leading jurors to be overly confident in the accuracy of the disclosure.

Although research demonstrates that hearsay witnesses leave out a substantial amount of information about how the child’s statement was elicited, jurors’ reactions to hearsay testimony do not suggest that jurors are sensitive to this lack of information. For example, mock jurors exposed to typical gist hearsay testimony tend to think that children were interviewed in a less suggestive manner than jurors exposed to the actual interview. Therefore, jurors who were only exposed to hearsay testimony did not seem to understand how the interview of the child was really conducted. Also, in research involving child sexual abuse cases, adult hearsay witnesses are generally seen as more accurate, confident, consistent, truthful, in possession of better memory abilities, and less suggestive than child witnesses. And not surprisingly, hearsay testimony tends to be at least as effective as the child’s testimony in producing pro-prosecution ratings and more effective than having no witness testify.

HELEN LEGIDO-QUIGLEY

Specific characteristics of an individual trial are also likely to influence trial results in cases involving hearsay testimony. For example, the exception under which hearsay is admitted, the child’s or the hearsay witness’s appearance of credibility, the nature of the abuse, the use of multiple hearsay witnesses, and the child’s demeanor when testifying are all likely to affect trial results. However, these case characteristics have yet to be explored through research.

**HEAVEN**

*Heaven* is one of the most common names for a positive location or situation for humans in the afterlife. Different religions use different names for such an otherworldly circumstance, but few fail to minister to the human impulse and need to imagine and realize some sort of continuation or transformation of life after physical death. Until recent times life expectancy was very brief. People had to see their parents die young and, healthcare being what it was, they often saw their children die as well. In the face of this sense of loss, it was only natural that human yearning for meaning and reward focused on some sort of heaven. Participants in various faith communities (i.e., “religions”) have often borrowed details of heaven envisioned by other faith communities.

At other times, visionaries within one religious tradition might reject the heaven in other traditions, as they vied for supremacy. These competing visions of heaven were both natural and useful; natural because human life took on more value with the promise that it would be extended or transformed, and useful because claims about heaven attracted new adherents and could not be disproved by rival claims. Seers, prophets, revealers, and authors of holy books could claim to have come from or visited other realms, but in normal human experience people did not have neighbors or fellow worshipers who had returned to earth or come back from the dead to report on the place that was their reward and destiny. The absence of certifiable signs did not mean the end of heaven; if anything, it stimulated imaginations. Heaven came to be a major aspect of revelation in most holy books.

Ideas of heaven that can be traced to ancient Egyptian and Mesopotamian civilizations have been highly influential on Western conceptions of the afterlife. These cultures did not leave written descriptions of heaven, but their conceptions of the afterlife can be deduced from temples, tombs, and monuments. Egyptian heaven, judging from representations in art adorning pyramids and tombs, was an attractive stage or place for pharaohs and other exalted humans, who needed sustenance and comfort and were served by slaves in the life to come. In Mesopotamia, evidence suggests, people believed that heaven was “above,” and references to a vertical dimension are present in many depictions of ritual found in tombs. “Heaven” was less often found on the horizontal level, though some paradises were pictured as bountiful and blessed utopias established here on earth. “Heaven” was still less frequently “below,” and what lay there was usually a shadowy nether existence or a place of eternal misery. Even in the modern world, believers in many faiths picture a literal place “up there”; all but instinctively, people look up or point up to locate heaven.

Among the Semitic peoples, who were most influential in the development of Judaism, Christianity, and Islam, the dominant concepts of the afterlife originated in Israel and in the Hebrew Scriptures. It surprises many whose faith derives from Hebrew scriptures that no very vivid heaven is promised or pictured in them. The abode of the dead was Sheol, a largely featureless and limited place. In later Judaism, as a reaction to captivity, military defeats, and other disasters, many in Israel did begin to make apocalyptic predictions. Many of these predictions were of coming catastrophes, but some foresaw the arrival of the Creator, the God of Israel, and a coming heaven on earth. In this environment, Jesus of Nazareth could take
for granted contemporary pictures of heaven, fostered mainly by the party of the Pharisees, just as he could point to another school, the Sadducees, as being deficient because they did not believe in an afterlife.

The New Testament offers many promises and pictures of paradise or heaven, the reward of those who properly follow Christ, or the gift to those who believe in him. For Christians, Paradise meant being in the presence of God, along with angelic beings and other "saints," amid pleasures revealed in parables or vividly described in the visionary biblical books. During Christianity's first three centuries, many Christians endured persecution, which proved a great stimulus to the paradisiacal imagination. When Christianity began to prosper and become established, Christian images of heaven and its promises took on triumphal and lavish elements.

In the modern world, in the face of new understandings of the physical universe, heaven as a place "above" survived only metaphorically and was regarded by many as an obsolete concept. At the same time, opinion polls continually found clear majorities believing in some sort of heaven. As people became aware of cultures other than their own, they also learned of the vision of heaven in other religions. Muslims and Christians, especially when in conflict, came to be aware of each other's promises. In the Qur'an, poetic language and lavish promises of paradise inspired Muslims to devotion, but also often inspired jihad ("holy cause") and even martyrdom. Anti-Muslim propagandists publicized and exaggerated some references in the Qur'an to virgins who would be at the command of martyrs in heaven.

Buddhism teaches the concept of Nirvana, a means by which or a place where one is removed from the trials and suffering of this world, though Buddhists do not equate Nirvana with heaven. Hindus in their many texts and religious expressions have imagined many benign and blissful versions of an afterlife, including a kind of heaven, Swarga loka, where one remains only temporarily. In Hinduism, revealed and foreseen heavens tended to be paired, as they are in other faiths, with prescriptions on how to live in order to attain them.

For all the belief in heaven, it must be said that often it has become recessive in religious teaching. Karl Marx thought of religion as the opium of the people, offering a haven in a heartless world and what critics colloquially dismissed as "pie in the sky by and by." Many of the faithful professed that they were not believers in God in order to get such rewards, but for intrinsic reasons. If the belief in heaven as a reward survives, it must be said that for many this belief is casual, minimal, not a primary motivating force. At the same time, as funeral liturgies and sermons in some religions, notably Christianity, suggest, preaching about an angel-filled heaven of bliss serves as a comfort to millions who mourn a departed loved one.

HECKMAN SELECTION CORRECTION PROCEDURE

The Heckman selection correction procedure, introduced by American economist James J. Heckman, is a statistical solution to a form of sample selection bias. Sample selection bias can emerge when a population parameter of interest is estimated with a sample obtained from that population by other than random means. Such sampling yields a distorted empirical representation of the population of interest with which to estimate such parameters (Heckman 1990), possibly leading to biased estimates of them. Heckman (1979) was specifically concerned with this possibility in a certain regression context.

Suppose that we are interested in estimating the population regression model

$$y = \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + \epsilon,$$

With a truly random sample from the population of interest, it should be straightforward to estimate $\beta_0$, $\beta_1$, and $\beta_2$ via ordinary least squares. Suppose, however, that we observe $y$ only if the units of observation in that random sample make some decision. For instance, we might observe $y$ only if
or

\[ e_2 = -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2 \]

This allows us to characterize the sample selection bias that might emerge from attempting to estimate the regression with only the subsample for whom we observe \( y \).

We wish to evaluate the population expectation

\[
E(y) = E(\beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + \varepsilon) \\
= E(\beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon)) \\
= \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2
\]

However, if we observe \( y \) only when \( v^* > 0 \), available data allows us to evaluate only the expectation

\[
E(y) = (\beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon) \mid v^* > 0) \\
= \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon) \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2
\]

In this setting, it will generally not be possible to separately identify \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \). To see this more clearly, assume that

\[
E(\varepsilon \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) \neq 0
\]

and consider a linear approximation of \( E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) \);

\[
\bar{e}_1 + \bar{e}_1 \cdot x_1 + \bar{e}_2 \cdot x_2 + \xi
\]

where \( E(\xi) = 0 \). Then, the overall expectation that can be gleaned from available data would be

\[
E(y) = \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon) \mid v^* > 0 \\
= \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon) \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2 \\
= \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + \bar{e}_1 \cdot x_1 + \bar{e}_2 \cdot x_2 \\
+ \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2
\]

Thus, in general, one would not be able to recover valid estimates of \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \) with the subsample for which we observe \( y \). The only exception is when

\[
E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) = E(\varepsilon_1) = 0
\]

In other words, if \( e_1 \) and \( e_2 \) are independent, sample selection bias disappears.

The Heckman selection correction procedure can recover unbiased estimates of \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \) with available data (i.e., where \( x_1 \) and \( x_2 \) are observed for the full random sample from the population of interest and \( y \) is observed only for the subsample for which \( v^* > 0 \)). The departure point for this technique is to recognize that the sample selection bias problem really stems from a type of specification error. With the subsample for which \( y \) is observed we estimate

\[
E(y) = \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon) \mid v^* > 0 \\
= \beta_0 + \beta_1 \cdot x_1 + \beta_2 \cdot x_2 + E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2)
\]

The problem, from the standpoint of recovering unbiased estimates of \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \), is that we do not observe \( E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) \) (which is a function of \( x_1 \) and \( x_2 \)) and hence cannot separately identify \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \) from it. However, if one could form an estimate of \( E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) \) and regress \( y \) on \( x_1 \), \( x_2 \), and that estimate, it would be possible to identify separately \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \).

To form an estimate of

\[
E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2)
\]

the Heckman procedure begins by assuming that \( e_1 \) and \( e_2 \) follow a bivariate normal distribution with correlation \( \rho \). Then, using well-known properties of the bivariate normal distribution, we have

\[
E(\varepsilon_1 \mid e_2 > -\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) = \rho \cdot \sigma_1 \cdot \phi(-\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2) = \rho \cdot \sigma_1 \cdot \lambda(-\gamma_0 - \gamma_1 \cdot x_1 - \gamma_2 \cdot x_2)
\]

where \( \psi(\cdot) \) and \( \Phi(\cdot) \) are the normal density and cumulative density functions, respectively, \( \lambda(\cdot) \) is referred to as the inverse Mill’s ratio. An estimate of it can be formed from the fitted model emerging from estimation of a probit regression of a dummy variable indicating whether \( y \) is observed on \( x_1 \) and \( x_2 \). Once that estimate of \( \lambda(\cdot) \) has been formed, a second-stage regression of \( y \) on \( x_1 \), \( x_2 \), and that estimate recovers unbiased estimates of \( \beta_0 \), \( \beta_1 \), and \( \beta_2 \).

The two steps are: (1) Estimate the probit model under which the binary status of \( y \) (i.e., missing/not missing) is a function of \( x_1 \) and \( x_2 \). From the fitted model, form an estimate of the inverse Mill’s ratio \( \lambda(\cdot) \) for each observation in the subsample for which \( y \) is observed. (2) Regress \( y \) on \( x_1 \) and \( x_2 \), and \( \lambda(\cdot) \) with the subsample for which \( y \) is observed. Owing to heteroskedasticity concerns it is common practice actually to estimate the equation of interest via a procedure such as weighted least squares.

The estimated coefficient on \( \lambda(\cdot) \) in the second-stage regression is an estimate of \( \rho \cdot \sigma_1 \). A test of its significance is thus in practice a test for correlation between \( e_1 \) and \( e_2 \). Since \( e_1 \) and \( e_2 \) are assumed to follow a bivariate normal distribution, this is tantamount to testing whether they are independent. There is a full-information maximum-likelihood version of this model, but this “two-step” procedure has been more widely utilized in applied work.

A few caveats are in order. First, in the decade following its introduction, it became increasingly clear that the model often performs poorly without some source of identification beyond the assumption of joint-normality of the errors \( e_1 \) and \( e_2 \). Technically, it should be identified by the nonlinearity of the inverse Mill’s ratio (which arises naturally from the assumption of joint normality). The
underlying reason for the poor performance evident in some applications is that the inverse Mill’s ratio is nearly linear over much of its range, introducing potentially severe multicollinearity between \( x_1 \) and \( x_2 \) and the inverse Mill’s ratio during the second-stage regression. The best remedy for this problem is to introduce an instrument \( z \) to the first-stage probit estimations that provides some source of variation in the inverse Mill’s ratio unrelated to that provided by \( x_1 \) and \( x_2 \).

Second, there have been growing warnings about misapplication of the model (an excellent example of such a critique is presented by William Dow and Edward Norton [2003]). The basic concern has been with the popularity of the Heckman procedure in applications where a continuous dependent variable \( y \) is characterized by significant mass at zero (with the first-stage probit component used to explain whether \( y = 0 \) or \( y > 0 \) and the second-stage linear regression component applied to the subsample for which \( y > 0 \)). However, the Heckman procedure is appropriate only in cases where the zeroes emerge from the censoring of some true value for \( y \). In cases where the zeroes are valid values for \( y \), and as such represent a legitimate corner solution for that variable, some other tool (such as the two-part model) might be more appropriate.

Even in the face of variation in common first and second stage regressors sufficient to exploit non-linearity in the inverse Mill’s ratio (which might obviate the need for first-stage identifying instruments), the model still relies on an assumed joint normality of errors to achieve identification by non-linearity. If the error terms are not in fact jointly normally distributed, the parameter estimates provided by the Heckman selection correction procedure might be biased (and, depending on the precise nature of the problem at hand, the degree of bias might exceed that which would result from simply ignoring the censoring and estimating the equation of interest over only those for whom the outcome \( y \) is observed). A variety of alternatives to the assumption of joint normality have been proposed in response to this. In principle, one tack would be to rely on different parametric joint distributional assumptions. However, since most of the readily obvious alternatives would likely involve no less heroic an assumption than joint-normality, the focus has instead shifted to more semiparametric approaches that rely less on explicit assumptions regarding the joint distribution of the error terms.

**HECKSCHER-OHLIN-SAMUELSON MODEL**

The Heckscher-Ohlin-Samuelson model attempts to explain the composition of trade between countries and the implications of trade for income distribution within the countries. The seminal work was presented in a 1919 Swedish paper (English translation, 1950) by Eli F. Heckscher (1879–1952) and a 1933 book by his student Bertil Ohlin (1899–1979). In later articles (especially 1949 and 1953–1954), Paul A. Samuelson added substantial rigor to the analysis and expanded the original Heckscher-Ohlin model. The analysis has been subjected to countless empirical tests to determine its applicability to actual trading patterns.

Building upon the earlier classical (David Ricardo [1772–1823]) comparative advantage trade model, the Heckscher-Ohlin-Samuelson model (hereafter H-O-S) goes behind comparative advantage to ask, “What determines comparative advantage in the first place?” The H-O-S answer is found by utilizing Heckscher’s observations that (1) countries differ in their relative endowments of the factors of production, and (2) production processes for different goods employ different relative intensities of the factors. Suppose a situation with only two factors of production (e.g., labor and capital, where “capital” refers to plant and equipment used to produce output), two goods (e.g., clothing and automobiles), and two countries (e.g., A and B). If labor is more abundant (in greater supply) relative to capital in country A than in country B, then, other things being equal, labor will be relatively cheaper in A than in B. That is, the wage rate in A (\( w_A \)) divided by the return to capital in A (\( r_A \)) will be less than the ratio of the corresponding values in B (\( w_B/r_B \)). If clothing production is specified to use more labor relative to capital than automobile production, then, because labor is cheaper in A than in B, country A will be able to produce clothing at a relatively lower cost than country B. By parallel reasoning, with abundant capital in B and capital-intensive automobile production, autos will be relatively cheaper in B than in A. Hence, the trade pattern is that A exports clothing to B, and B exports automobiles.
to A. This is the *Heckscher-Ohlin theorem*: a country exports goods that are produced relatively intensively by the country’s relatively abundant factor of production, and imports goods that are produced relatively intensively by the country’s relatively scarce factor of production. The formal analysis contains many underlying assumptions, but this trade pattern conclusion is straightforward and accords with common sense.

Besides predicting trade patterns theoretically, H-O-S also yields implications of trade for factor prices and income distribution in the countries. As trade begins in the above example, there will be greater relative demand for A’s abundant factor (labor) in order to produce the new clothing exports; there will be less relative demand for the scarce factor (capital) due to the reduced need for domestic auto production because of the auto imports. These changes mean that \( w_A \) will rise and \( r_A \) will fall, so \( (w_A/r_A) \) rises. At the same time, \( w_B \) will fall and \( r_B \) will rise [so \( (w_B/r_B) \) falls] as country B demands relatively more capital to produce auto exports and relatively less labor to produce clothing. These factor price changes continue until an equilibrium is reached where there is no further upward or downward pressure on any factor return. Before trade, \( (w_A/r_A) < (w_B/r_B) \) but, with trade, the rise in \( (w_A/r_A) \) and the fall in \( (w_B/r_B) \) cause these ratios to converge. In equilibrium, \( (w_A/r_A) = (w_B/r_B) \). Given the assumptions of the model, not only relative factor prices but also absolute factor prices across countries are equalized, meaning that \( w_A = w_B \) and \( r_A = r_B \). If equality is not reached, trade continues to expand until it is. This powerful implication of trade for factor prices is known as the *factor-price equalization theorem*. While such equalization clearly does not happen in practice, it is the convergence or the tendency toward equalization that is important.

Even more powerful in H-O-S is the extension of the factor-price analysis to the result known as the *Stolper-Samuelson theorem*—a country’s scarce factor of production loses real income from trade (and gains from restrictions on trade) and the country’s abundant factor of production gains from trade (and loses from trade restrictions). These outcomes occur because of the changing demands stated above. Hence, trade policy becomes intertwined with politics—in country A in our example, labor favors trade because labor’s real income thereby increases, while owners of capital lose and would oppose trade.

Finally, a fourth major theorem that arises from H-O-S is the *Rybczynski theorem*. This theorem states that an increase in the supply of a factor of production in a country (say, labor) leads to an increase in output of the good that uses that factor intensively (clothing) and to a decrease in production of the other good (autos). Thus, H-O-S has a growth dimension with implications for future output and future trade patterns.

Empirical testing of H-O-S has centered around examining whether actual trade patterns correspond to the model’s predicted patterns. An early test (1953) by Wassily Leontief (1906–1999) surprised economists because the results suggested that the relatively capital-abundant United States was exporting labor-intensive goods and importing capital-intensive goods. This “paradox” led to much later testing that included a greater number of factors (e.g., by dividing labor into different skill categories) and different testing techniques. Some studies, such as those by Daniel Trefler (1995) for thirty-three countries and nine factors and by Harry P. Bowen, Edward E. Leamer, and Leo Sveikauskas (1987) for twenty-seven countries and twelve factors, found limited verification of the predicted patterns. When adjustments are made in the literature for elements outside the model, results get better for H-O-S, but much trade still goes “unexplained.”

Another aspect of H-O-S that has been empirically investigated concerns the Stolper-Samuelson theorem, in that economists have sought to determine whether, particularly in the United States, relatively unskilled labor (a scarce factor in the United States) has lost real income because of increased trade. This research, done in the context of the observed increased inequality in income distribution in the late twentieth century, is generally regarded as having found some small effect in the expected direction but also as having found that the growing inequality was due more importantly to the nature of technological change. Empirical work as well as other considerations regarding H-O-S have led to a recognition that the theoretical model, while widely employed, can be criticized for lack of attention to “real-world” characteristics such as differing production functions across countries, economies of scale, and product differentiation.

HEDGING

Hedging is the process of using derivative financial instruments to reduce the price risks that either arise in the course of normal business operations or are associated with investments. Hedging is one of the most important functions of financial markets. Traders performing hedging transactions are hedgers. Hedgers are often investors, producers, or major users of a given commodity who have preexisting risks associated with the price fluctuation of the specific investment or commodity.

There are many ways that hedging can be carried out through derivative instruments—that is, financial instruments that derive their values from the underlying assets, such as futures contracts, forward contracts, options, and swap agreements. For example, a futures contract allows the holder to carry out a transaction in the future at a price determined in the present. The value of the contract therefore depends upon the asset or commodity underlying the transaction. Hedging with futures contracts is fairly straightforward. Hedgers can hedge by either buying or selling futures contracts as a temporary substitute for a transaction to be made in the spot market. As long as spot and futures prices move together, any loss realized on one market (whether spot or futures) will be offset by a profit on the other market. Using options for hedging purposes is more complicated as it requires an analytical determination of the appropriate number of options contracts to buy or sell.

As an example of hedging with futures contracts, consider a corn farmer who anticipates selling certain bushels of corn three months from now and is concerned that the price of corn might fall in the next three months. The farmer may sell corn futures contracts for hedging. If corn prices in both spot and futures markets fall, the loss on the spot market will be offset by the profit on the futures market. Another example is related to a food-processing company that plans to purchase corn and is concerned that the price of corn might rise. The company can buy corn futures contracts for hedging. If the corn price rises, a loss on the spot market is met with a profit on the futures market, resulting in a reduced price risk.

A hedge is perfect if the gain (or loss) on the futures market matches perfectly with the loss (or gain) on the spot market. In practice, hedging may not be perfect because the difference between the spot price and the futures price (that is, the basis) may not converge to zero at the time the futures position is closed. Hedging effectiveness measures the extent to which the price risk is reduced through hedging. A hedge ratio is the number of derivative contracts transacted to reduce the price risk of a given position in the underlying asset. Hedging strategies are formed to choose the suitable derivative contracts and the amount of such contracts to be used. Traditional views hold that the optimal hedging strategy is one that maximizes the expected utility or minimizes the variance of the value of the hedged portfolio. Recent developments explore alternative approaches. For example, it is argued that a one-sided measure for hedging, such as the downside risk, is more accurate.

With the internationalization of financial markets, currency derivative instruments have increasingly been used to hedge currency risks in an international portfolio, which usually contains multiple risks. Optimal coordinated hedging strategies, which consider the effects of correlation among multiple risk factors in a portfolio, can be applied to hedge multiple risks and to achieve optimal hedging effectiveness.

The recognition of hedging as a purpose of derivatives transactions is important. Accounting rules treat the changes in the fair value of derivatives differently depending on the purpose for which the derivatives positions are entered. New derivatives that have been developed recently are intended to reduce quantity or revenue risks, which may complicate the appropriate accounting treatment.

HEDONIC PRICES

Hedonic prices reflect the value of differences in the quality of goods. Hedonic price models provide a useful way of comparing the prices of heterogeneous goods of differing quality so long as consumers are not themselves using prices to judge quality (consumers are assumed in these models to compare the quality of goods independently of their prices). In hedonic models, goods are seen as being produced with different characteristics, and the quality of these goods reflects differences in the mixture of these characteristics. In making a purchase, consumers consider both the quantity of the good that they purchase and the quality of the good. The quality of the good is reflected in the price consumers are willing to pay. This tradeoff between quality and quantity is central both to models of hedonic prices and to household production theory.

In hedonic pricing models, both the characteristics and the prices are known. Differences in the prices of heterogeneous goods are viewed as reflecting quality differences resulting from different characteristics. For example, in a 1928 study, Frederick V. Waugh viewed the perceived quality of asparagus as being determined by the greenness of the asparagus and the size of the stalk. Greenness was held to be positively related to perceived quality, while stock size was held to be negatively related to perceived quality.

The price of other heterogeneous goods can be, and has been, similarly modeled as a function of a vector of characteristics of that good. Examples include automobiles, houses, and computers. To model the price of a particular version of a heterogeneous good, let \( P_i \) be its price, let \( C_i \) be a vector of \( m \) characteristics and let \( e_i \) be a stochastic error term. If there are \( n \) different versions of the good, the price of each version might be written as:

\[
P_i = \beta_0 + \beta_1 C_{i1} + \beta_2 C_{i2} + \ldots + \beta_m C_{im} + e_i
\]

A hedonic price index can then be created as the characteristics and prices of the good change through time.

Hedonic price models have been applied to the construction of price indexes of goods such as automobiles, houses, and computers, for which the characteristics (quality) of the good have been changing over time. They have also been applied to estimates of the quality of life in different locations. The quality of regional amenities is assumed to be capitalized into housing prices and what is commonly thought of as the cost of living. Larry Sjaastad, in a 1962 article, argued that the only way that families can purchase the amenities that a location offers is to migrate to that location. Hence, housing prices are, in essence, the hedonic prices of those amenities. In 1979 Sherwin Rosen developed a hedonic method for measuring the quality of life within a region, based on the assumption that differences in regional amenities are capitalized by lower wage rates and higher housing costs for an amenity-rich region. A hedonic index of regional quality can then be estimated as a function of the characteristics of the location.

The hedonic model of regional quality is an extension of a model in public economics created by Charles M. Tiebout in 1956. Tiebout was concerned about the allocation of local public goods, and he developed a model based on the competition between locations for new residents. Cities attract residents by providing local public goods, and consumers are held to be aware of the public goods and the taxes of different regions, and they then move to the region that has the profile of public goods that maximizes their individual utility. Taxes are simply the prices of these public goods. Hedonic migration models extend Tiebout’s model by including amenities provided by nature and the private sector alongside publicly provided amenities in determining the quality of life in various locations. Tiebout’s model can also be made more general by including housing costs in determining the migration decision.

HEDONISM

**SEE** Farsightedness.

HEGEL, GEORG WILHELM FRIEDRICH

1770–1831

Hegel is a difficult thinker. The complexity of the arguments of his major works—the *Phenomenology of Spirit* (1807), the *Science of Logic* (1812–1816), the *Philosophy of Right* (1821), and the lectures on aesthetics and world history, which are, perhaps, the least inaccessible—defies capsule summarization. Yet a characterization of the major concerns that connect Hegel’s writings can be essayed readily enough.

The recent florescence of interest in Hegel among English-language philosophers is a development no one predicted forty years ago. Yet there are good reasons why it has taken place. First and foremost, Hegel (unlike his contemporary Immanuel Kant) emphasized the historically located character of our thinking. Nothing exists out of history; once nature and religion wane as validations, only history is left. The *Philosophy of Right* characterizes philosophy as “its own time apprehended in thought.” The facts of history, which add up to a process, are the raw material to which the philosopher gives form and meaning. Reason is dynamic, kinetic; its content unfolds over time. History, which Hegel painted in broad strokes, is a rational process of development; progress in freedom and progress in thought are linked.

Although Hegel, secondly, is a precursor of Karl Marx (1818–1883) and Marxism, he believed that philosophy has no business “giving instruction to what the world ought to be”; over and above the still-vexed issue of Marx’s “materialism” versus Hegel’s “idealism,” Hegel, for his part, emphasized philosophy’s retrospective dimension, not its prospective implications. Philosophy is *Nach-denken* (“thinking after the fact to be thought about”). It interprets the present in light of the past. “The owl of Minerva,” as Hegel famously put it in the *Philosophy of Right*, “spreads its wings only with the falling of the dusk.” We may advance views only when the time is ripe. It makes sense to see Hegel not only as a post-Enlightenment and post-Kantian thinker, but also as a post–(French) Revolutionary one. He at first welcomed the Revolution, only to recoil from the Terror—deficient principle run riot and eventuating in disaster. Hegel had had no love for the ancien régime, but he was infuriated by the revolutionaries’ failure to replace it with anything more substantial or enduring.

But what makes Hegel post-Kantian? After all, his *idée maîtresse*—that we are free only when we act in accordance with our reason—is eminently Kantian. What separates Hegel from Kant is what he does with this conviction. Kant’s notions of freedom and morality derive from a categorical imperative figurable by pure reason. This to Hegel—who did not believe in “pure” reason—was formal and skeletal. It lacked the substance that “ethical life” (the customs and mores that situate us in a particular time and place) alone can provide. “Ethical life” is an *historical* category, not an abstractly rational one; “abstract,” meaning partial, unsubstantiated, fragmentary—the part standing for the whole as in a synecdoche—is always used pejoratively by Hegel. The battle lines are arrayed from book to book: Particularity, subjectivism, and disruption are on the negative side of the ledger, whereas substance, connectedness, coherence, and unity rest on the positive side. Hegel was relentlessly opposed to every source of disconnection he could identify. Then as now, there was no shortage of contenders: The atomistic individualism that threatened in the early nineteenth century to dominate the German as it had the British economy was but one of them.

Hegel’s ledger (with these two sides counterposed) has a political, not to say utopian implication that was not to be lost, either immediately on the Young (left) Hegelians or later among twentieth-century critical theorists. This is that if history, rationality, and “ethical life” could be harmonized, the result would be an ethical community in which we could fulfill our own potentialities as we contribute to the well-being of the whole to which it is ours to belong. *This* ideal, not Kant’s arbitrary distinction between noumena and phenomena, is the true legacy of the Enlightenment. Kant had mapped out a no-man’s-land by declaring certain issues unknowable. Hegel, by contrast, held that nothing is beyond the scope of human thought—despite (or because of) the false starts, falterings, stumblings, and blind alleys almost gleefully detailed, serially, throughout the *Phenomenology of Spirit*. 

Hegel’s notion of Geist, renderable either as “spirit” or “mind,” has seemed amorphous, threatening, or both to English-language commentators, some of whom suppose that Geist (along with its corollary, “the cunning of reason”) signifies a superhuman demiurgos pulling the strings of “its” human puppets. This is not what Hegel meant. Geist is both how a community understands itself, gives itself form and content, and the way the individual knows him- or herself through the community of which he or she is a constitutive part. Either way, it forms identity. Hegel distinguishes “objective” from “absolute” spirit. The former, the subject matter of the Philosophy of Right, is the institutional framework for the latter, which finds expression in our “spiritual” pursuits: art, religion, and (most importantly) philosophy. “Objective” spirit is anything but its own justification; there is nothing ultimate about it. “Absolute spirit” in its ultimate form, philosophy, can account for “objective spirit,” its precondition. “Objective” cannot account for “absolute” spirit in anything like the same way.

Hegelianism, as John Toews makes clear, enjoyed some philosophical and even some institutional purchase in Germany, though the latter in particular petered out during the 1840s. Hegelianism remained strong enough to provoke Søren Kierkegaard (1813–1855) through several important books: In Britain, however, where it was introduced (after a fashion) by James Hutchison Stirling’s The Secret of Hegel (1865), its adoption by Idealists (T. H. Green, F. H. Bradley, Bernard Bosanquet, J. T. E. McTaggart) served mainly to buttress the Idealists’ positions déjà prises (preconceptions); Hegel influenced Pragmatism in the United States via Josiah Royce and John Dewey; in Italy he influenced Benedetto Croce and Giovanni Gentile. Hegelianism was particularly influential in France: On Hippolyte Taine and Ernest Renan in the nineteenth century, and on Alexandre Kojève (whose lectures in the 1930s attracted the interest of Jean Hyppolite and Jean-Paul Sartre, among many others) in the twentieth.

HEGELIANS

In the opening years of the twenty-first century, the enormous influence of Georg Wilhelm Friedrich Hegel (1770–1831) within the social sciences shows no sign of lessening. This influence is strongest and most obvious in historiography, political theory, and sociology, a discipline that is difficult to imagine in the absence of Hegel. Modern philosophy of religion is similarly inconceivable without Hegel. Hegel’s analysis, in The Philosophy of Right, of capitalist “civil society” and the poverty it inevitably generates is one of the most important early instances of social (as opposed to political) theory, and it decisively shaped Marx’s critique of alienated labor and the history of class struggle, as well as the Frankfurt school’s analysis of the “Dialectic of Enlightenment” in the 1940s. Through Alexander Kojève’s lectures in 1930s Paris, Hegelian themes were absorbed by Jean-Paul Sartre, Jacques Lacan, and Maurice Merleau-Ponty, and they were passed on in their contributions to existentialism,
psychoanalysis, and phenomenology, respectively. Another set of Hegelian concerns was crucial to the “communitarian” critique of Rawlsian liberalism in the 1970s and the “politics of recognition” of Charles Taylor, Axel Honneth, and Nancy Fraser in the 1990s. Even as a bogey to be challenged, Hegel has been crucial. For example, Bertrand Russell and G. E. Moore gave birth to Anglo-American analytic philosophy in rebelling against the Hegelian orthodoxy of late nineteenth-century Britain, and much contemporary post-structuralism and postmodernism continues to take Hegel as its great adversary.

Hegel has played an important role in such varied settings in part because of the extraordinary breadth and depth of his work, and in part because of the immense difficulty this poses for the interpreter. While still alive and lecturing at the University of Berlin, he replaced Immanuel Kant, Johann Fichte, and his former schoolmate Friedrich von Schelling as the dominant philosophical figure of his age in Germany. Even then, the meaning of Hegel’s teaching was hotly contested, and Hegel quipped that none of his students understood him—with the exception of one, who misunderstood him. “Old,” or “Right,” Hegelians emphasized the commitment to the status quo in Hegel’s infamous claim that “What is rational is actual (wirklich), and what is actual is rational,” while “Young,” or “Left,” Hegelians emphasized the commitment to reason (Vernunft).

As with later battles over Hegel, each side in this contest advanced a partial, and hence misleading, account of the matter. Though it still largely determines the popular judgment of Hegel, the Right Hegelian interpretation is most obviously lacking, for Hegel himself took care to distinguish actuality from the “superficial outer rind” of the merely existent; he asked, sarcastically, “Who is not clever enough to see much in his environment that is not in fact as it ought to be?” To argue that the real is rational is in part to define the real as something more than the merely existent, as non-Hegelians do when they castigate a poor teacher for not being a “real” teacher. Just as not all teachers are real teachers in this sense, so not all states are real states for Hegel. In particular, the Prussian and Nazi states, for which he has been wrongly blamed, fail to meet the rational standards of the real in modern times, standards that in Hegel’s own account include a constitutional monarch, trials by jury, parliamentary government, freedom of conscience and of the press, and the other prerequisites of individual autonomy.

In all his writings, Hegel struggled to find a way to relate the individual to the greater community that escapes the alienation and “positivity” of an externally imposed law backed only by custom and the threat of force. His initial attempts in this regard center on love, life, and some form of Volksreligion as modes of experience that attain this moment of community without the sacrifice of individuality. In his mature political philosophy, Hegel used the less religious term freedom to characterize the state of being at home in another (Beischelbstsein in einem Anderen) in which one is neither opposed by an alien, hostile world nor engulfed in an unmediated totality that is equally inhospitable to the claims of individual fulfillment. Hegel argues that this is attainable only in a modern polity that the individual can recognize as the precondition and expression of its own freedom.

If the Left Hegelians properly appreciated this, Marx (the most famous of them) nonetheless advanced his own profound misunderstandings of Hegel, misunderstandings that persist to this day. The most significant of these concerns his interpretation of Hegel’s understanding of the dialectic that shapes both history and reason. Marx has passed on to millions a bowdlerization of Hegel developed by Heinrich Chalybäus, according to which the dialectic can be easily broken down to a cookie-cutter triad of thesis, antithesis, and synthesis. But these were never used as terms of art by Hegel himself, who described “this monotonous formalism” as “a lifeless schema.”

For Hegel, the dialectic is a means of conceiving of both history and reason as processes centering upon negation. In the case of the former, this reflects the goals of Hegel’s theodicy, his attempt to demonstrate that, appearances notwithstanding, the bloody history of the West has a rational structure and outcome. In the case of the latter, it is an attempt to overcome the aporias of Kant’s theoretical and practical philosophy, and to give an account of subjectivity that neither rests upon an incoherent conception of a thing-in-itself nor sacrifices human autonomy to heteronomous forces. Only by means of a dialectical philosophy in which what is contains its own negation can Hegel argue, as he does in the Philosophy of Right, that an understanding of the moral and political structures required by the free will can be generated from out of that will itself. Here, as elsewhere, negation takes the form of sublation, an awkward term used to translate Hegel’s Aufhebung, the simultaneous destruction and preservation—at a higher, more rational (and hence real) level—of what is. If Hegel’s account of this process is hardly without problems, it remains one of the most important attempts to develop a conception of reason that does not stand aloof from history and society, but rather engages with the details of their unfolding.

HEGEMONY

The concept of hegemony has been central and most developed in the work of Antonio Gramsci, the leading Italian Marxist intellectual who spent the last eleven years of his life in Benito Mussolini’s prisons between 1927 and 1935. Gramsci defined hegemony as a condition under which a group establishes its supremacy not only by physical force but also through a “consensual submission of the very people who [are] dominated” (Litowitz 2000, p. 518). However this notion of hegemony has a long history and multi layers and it is important to unravel its complete meaning to understand its significance in Gramsci’s adoption of the concept.

According to Raymond Williams the word hegemony probably comes from the Greek word egemoni whose root is egemon, meaning “leader, ruler, often in the sense of a state other than his own” (1976, p. 144). From the nineteenth century onward hegemony came to indicate a “political predominance, usually of one state over another” and subsequently described a “policy expressing or aimed at political predominance” (p. 144). In his Antinomies of Antonio Gramsci (1976), Perry Anderson points out the concept of hegemony or egemoniya that had started to emerge in the writings of Georgi Valentinovich Plekhanov (1856–1918), a Marxist theoretician and founder of the Social Democratic movement in Russia, was subsequently used by the Russian Marxists as a central political slogan during the Russian Social Democratic movement from 1890s through the Bolshevik Revolution in 1917. Russian Marxists used hegemony to refer to the political struggle and leadership by the working class to overthrow the tsarist rule in Russia. This emphasis placed on the primacy of the working class to acquire hegemony in the bourgeois revolution in Russia was further developed by Vladimir Lenin especially in What Is to Be Done, written in 1902.

The notion of hegemony so far debated in the works of Russian theorists gained an international valence through the first two World Congresses (1919, 1920) of the Third International (1919) and emphasized the need for the proletariat to exercise hegemony in order to form alliance with other exploited groups to struggle against capitalism in the Soviet Union. However, according to Perry Anderson it was in the Fourth Congress (1922) of the Third International that hegemony for the first time also included the idea of “domination of the bourgeoisie over the proletariat, if the former succeeded in confining the latter to a corporate role by inducing it to accept a division between political and economic struggles in its class practice” (1976–1977, p. 18). It was this notion of hegemony brought forth in the Third International that seemed to have influenced most Gramsci’s conceptualization of the term.

In accordance with the principles of the Third International, Gramsci defined hegemony as class alliance of the proletariat with other peasants to forge a common struggle against capitalism. This notion of hegemony included the need for certain “concessions” or “sacrifices” necessary on the part of the proletariat to be able to include the needs and interests of the group over which hegemony is to be exercised without resorting to win them over through violence.

However as Douglas Litowitz pointed out in his 2000 article, “Gramsci, Hegemony, and the Law,” Gramsci’s view of hegemony changed when he noticed that in Italy under the fascist dictatorship of Mussolini the very people who were exploited by fascism and capitalism willingly consented to their exploitation. Thus Gramsci concluded that domination could be exercised not only through physical force but also through persuasion, when the dominant group is able to disseminate its values through mediums such as church, schools, or popular culture. This consensual hegemony is not only economic but also political and cultural as well. In this conceptualization of hegemony as political and cultural, Gramsci was quite influenced by the Italian philosopher and politician Benedetto Croce’s (1866–1952) work on the role of culture and consent in politics.

According to Gramsci hegemony always has its basis in economy and “must necessarily be based on the decisive function exercised by the leading group in the decisive nucleus of economic activity” (Hoare, Quintin, and Smith 1971, p. 161). However his concept of “economic” is different from Karl Marx’s distinction between an economic base and a political and cultural superstructure and Marx’s assertion that only if the base changes, superstructure will change as well. Gramsci argued that dominance in eco-
nomic relations of production as well as means of production, although necessary, is not a sufficient condition for social dominance. Thus according to Robert Bocock (1986), by opposing the economic determinism of Marx, Gramsci emphasized the political and the cultural by including the state and the civil society as areas in which power is exercised and hegemony established.

Gramsci argued that while hegemony pertains to civil society, which is an ensemble of organizations, force/coercion belongs to the realm of the state. Within capitalism, state thus resorts to coercive domination to conform the popular mass to certain types of production and economy, while civil society exercises hegemony through cultural institutions such as the church, trade union, schools, media or through the print culture. Thus hegemony in this context refers to the cultural control or the “ideological subordination of the working class by the bourgeoisie, which enables it to rule by consent” (Anderson 1976–1977, p. 26). According to Anderson Gramsci has used this model to analyze the difference between Tsarist Russia and western Europe to imply that the tsars ruled by force while the British and French bourgeoisie by deception, flattery, and concessions.

This first model of hegemony by Gramsci underwent further mutations to give rise to a second model when hegemony is seen as being exercised not only by the civil society but by the state as well. Hegemony exercised by the state can be termed as political hegemony and the organs of political hegemony consists of executive, legislature and judiciary.

The third model of Gramsci erases the distinction between state and civil society so that “consent and coercion alike become co-extensive with the State” (p. 125). This was Gramsci’s idea of an “integral state,” a term he borrowed from the German philosopher Georg Wilhelm Friedrich Hegel (1770–1831). As Jeremy Lester (2000) noted, this concept of “integral state” encompasses a complex set of practices and activities through which the ruling class can not only dominate through force but obtain consent as well. Thus State embodies not only coercion but cultural and ideological hegemony as well. Gramsci used this model to elucidate how bourgeois capitalism maintains its rule over the working class through consensus as well as coercion. In this third model Gramsci, alludes to Niccolò Machiavelli’s conceptualization of “Centaur,” which is half beast and half human and a combination of the dual traits of fox and lion that is deception and violence respectively. Gramsci thus argued that in order to dominate, the state must include the dual levels of force and consent, domination and hegemony, violence and civilization.

Thus hegemony—by constituting a synthesis of political, economic, and cultural meanings and values and experienced and internalized by people who are exposed to it—plays a pivotal role in the process of normalization where such values appear to be “common sense” to those who are subordinated and hegemonized by the ruling group.

systematic tendencies leading to some “future immanent in the present” (1992, p. 381). Underlying the system’s movements were a variety of factors, both economic and noneconomic. In other words, the trajectory of the system is inseparable from both the wider sociopolitical context within which the economy is situated and the subjective drives and behavioral tendencies of historical agents, which both shape and are shaped by changing socio-economic and political structures.

Heilbroner’s initial fascination with the worldly philosophers’ prognoses led to his own analyses of the economic, political, cultural, and sociopsychological drives, motivations, and propensities underlying production, distribution, and exchange. In these investigations, Heilbroner adopted his own versions of Schumpeter’s (1954) notions of “vision” and “analysis.” Whereas for Schumpeter, analysis had a kind of “cleansing” effect, which prevented the necessarily ideological nature of the “pre-analytical cognitive act” from tainting the scientific endeavor, for Heilbroner, economic theory is inescapably value-laden. Biases are always present, at times lurking just beneath the surface, but often emerging in the form of assumptions that determine the content of analytical categories and the direction of prognostications.

Although Heilbroner’s explicit self-identification with a “hermeneutic” approach came relatively late, he had always emphasized that inquiry necessarily has an interpretive dimension. For Heilbroner, this meant that the very object of inquiry cannot be presumed self-evident. The “economy” is an abstraction from the social totality, and thus the defining of the subject matter of economics is a task that influences the nature and direction of analysis. Heilbroner long advocated “material provisioning”—the harnessing of society’s material resources to provide for the needs and wants of its members—as the central problematic of the political economist. He thus argued against any notion of universal economic “laws,” emphasizing the historical specificity of capitalism in human history. Heilbroner’s historical approach, rejection of universal laws, and refusal to “read” markets back into precapitalist societies provide a welcome respite from the “economics imperialism” of modern neoclassical economics.

In later years, Heilbroner questioned whether, under present contemporary circumstances, worldly philosophy is still possible. He believed that scenarios and visions do not lend themselves to formal analytical procedures. More importantly, he held the position that the economic behaviors that set the system on its path have become less dependable, while political intervention has become more strategic. An “instrumental” approach, in his mentor Adolph Lowe’s ([1965] 1977) sense, thus becomes more appropriate, with “blueprints depicting possible routes from present realities to desired destinations” replacing “scenarios depicting a future immanent in the present” (Heilbroner 1992, p. 381; Heilbroner and Milberg 1995, pp. 118ff; Forstater 1999).

Despite such skepticism, Heilbroner expressed the hope that the “irrelevant scholasticism” of contemporary neoclassical economics might be replaced with a reinvigorated political economy. Political economy may “perhaps [be] resurrected by a corps of dissenting economists,” employing a framework that: “take[s] full cognizance of the sociopolitical realities of our time, whatever the difficulties they may pose for the construction of elegant models… A rekindling of the tradition of political economy is within the realm of possibility. That would indeed be a happy ending to the teachings of the worldly philosophy.” (Heilbroner 1996, p. 336).

BIBLIOGRAPHY

HELL

The English word hell comes from hel, the abode of the dead and the underworld of Norse mythology. In the Bible, the Hebrew word Sheol and the Greek word Hādēs refer to the netherworld, a shadowy realm of the dead more than a place of torment (though some New Testament texts use Hādēs to refer to punishment or the dominion of death; see Luke 16:23, Matt. 16:18, and Rev. 6:8).

The biblical word for the state of postmortem punishment is Gehenna, from the Hebrew ge-hinnōm, an abbreviation for the “valley of the son of Hinnom,” a place south of Jerusalem known for idolatry and human sacrifice (see 2 Kings 23:10 and Jer. 7:31–32). In Jewish apocalyptic and rabbinic literature, Gehenna often refers to a
place of darkness, fire, and punishment for the wicked—a punishment variously conceived as everlasting, temporary, or ending in annihilation. In modern times, many Jews have rejected the concept of eternal damnation.

In the New Testament, Gehenna is used for the state of everlasting punishment and fire (see Matt. 5:22, Mark 9:43, and James 3:6), though the Greek word Tartarus does appear (see 2 Pet. 2:4). The concept of eternal punishment is expressed through images of “everlasting fire” (Matt. 18:8 and 25:41), “weeping and gnashing of teeth” (Matt. 8:12), “fire and brimstone” (Rev. 14:10), and a “pool of fire” (Rev. 19:20). People confined to the everlasting fire include those who despise the needy (Matt. 25:41–46), as well as “cowards, the faithless, the polluted, murderers, fornicators, sorcerers, idolaters and liars” (Rev. 21:8). In addition to damned humans, Satan and the fallen angels also receive everlasting punishment (see Jude 6, Matt. 25:41, and Rev. 20:10).

Christian theology developed an understanding of hell as everlasting punishment and exclusion from heaven. In the Middle Ages, temporary purifications after death (purgatory) were distinguished from the everlasting tortures of hell, as was the state of limbo, in which the souls of unbaptized babies and virtuous non-Christians were deprived of the beatific vision but did not suffer the torments of hell. Dante Alighieri (1265–1321) gave poetic expression to limbo and the levels of hell in his <i>Inferno</i>, the first part of his <i>Divine Comedy</i>, which continues with <i>Purgatory</i> and <i>Paradise</i>

Traditional Christians (whether Catholic, Orthodox, or Protestant) affirm hell as a true possibility, either for those who culpably reject the Christian Gospel or who die in a state of “mortal sin.” The everlasting nature of hell, even after the resurrection of the body, was affirmed at various Church councils (e.g., the local synod of Constantinople of 543 and the Fourth Lateran Council of 1215). Some Christians hope for universal salvation, but most Christian denominations still affirm the possibility of eternal damnation. Many Christians today believe that sincere non-Christians, who are outside of the Church “through no fault of their own,” might still achieve salvation (see <i>Catechism of the Catholic Church</i>, no. 847).

The ancient Greeks and Romans had multiple concepts of the underworld and the fate of the dead. In the mystery religions and fertility cults, Hādēs or the underworld played a prominent role in themes of death and rebirth. By the fifth century BCE (perhaps due to Egyptian and Persian influences), the Greeks had developed concepts of rewards and punishments after death, with Tartarus, the lower realm of Hādēs, as the place of punishment for the wicked. Platonism and Neoplatonism incorporated beliefs in reincarnation and the transmigration of souls, which made purification from wrongdoing achievable over multiple lifetimes.

In the ancient world, the Egyptians and the Zoroastrians from Persia were most pronounced in their affirmations of rewards and punishments after death. Around 1750 BCE, the Egyptian <i>Book of Going Forth by Day</i> or <i>Book of the Dead</i> described how the soul or heart of the deceased person is weighed on a scale balanced by the “feather of truth.” Rewards or punishments then follow (with complete destruction being one possibility).

The Persian religion of Zoroastrianism (from the prophet Zoroaster/Zarathustra, circa ninth or tenth century BCE) describes judgment after death as the crossing of the Chinvat Bridge toward Paradise. The souls of the wicked are tossed off the bridge into hell, whereas the righteous souls enter Paradise and other souls go to a state of limbo. At the end of time, the souls of the deceased are reunited with their bodies and experience a final judgment. The souls in limbo (and perhaps those in hell) then enter Paradise after a final purification. The evil spirit Angra Mainyu and other demons are, however, consigned to hell forever.

Islam, like Christianity and Zoroastrianism, affirms judgment after death and a future resurrection of the body, as well as rewards in heaven (paradise) and punishments in hell. Muslims believe that God (Allah) assigns certain angels to keep a record of human deeds, and this record will determine one’s fate after death. After death, those who are wicked begin to experience the hellfire—even in the grave prior to the Day of Judgment and the resurrection of the body. The righteous souls, in turn, begin to experience the rewards of Paradise, which continue forever after the reunion with their bodies. Some Muslims, following 2:262 and 5:69 of the Qur’án, believe that followers of other religions can escape hell and enter Paradise. Others, following 4:56, believe severe punishments await those who deny the Qur’án as God’s revelation.

Classical Chinese culture recognized some type of life after death, but a clear and consistent concept of hell never developed. Confucius (c. 551–479 BCE) was reluctant to talk about the afterlife, and Taoism tended toward a naturalism that denied personal survival after death.

Jainism, Hinduism, Buddhism, and Sikhism—the main religions originating in India—all affirm reincarnation and the transmigration of souls; moreover, Hindus and Buddhists recognize thousands of hells. Because of reincarnation, however, the possibility of eventual purification and deliverance is maintained, even if this liberation may require countless lifetimes.

The fear of hell remains a living reality among many people today, especially in Christian and Muslim circles. In modern secular societies, however, the word <i>hell</i> has
assumed a largely metaphorical meaning. Situations of poverty, violence, and devastation are described frequently as “living hells.” Many psychologists and sociologists understand hell as an archetype of the deepest fears of the human imagination, expressing the thoughts of torture, rejection, and abandonment that circulate within the human psyche.

HERD BEHAVIOR

The term herd behavior derives from the observation that animals that form part of a group sometimes mimic actions of either a leader or each other apparently without thought. In economics and financial markets, this term describes situations in which a large number of agents appear to be making similar decisions. Spurious herding results when decisions are similar, but based on independent analysis by agents. True herding results when decisions are based only on public information about the behavior of others, and private information is neglected. Herd behavior can have a detrimental effect on economic efficiency. It stands in contradiction to the basic tenets of efficient markets and to the claim of the superiority of the market system; it undermines the reliance on rationality that requires that agents base their decisions on all information. Modeling of herd behavior has only recently begun to shed light on its motivations and consequences.

A form of herd behavior results when information cascades develop in markets characterized by the high cost of information collection. When information collection is costly, an agent may make the same decision as previous agents and not seek any private information. The situation is exacerbated by the presence of moral hazards.

Portfolio managers may herd when their performance is evaluated relative to the market, and herding behavior can also be observed in the international lending decisions of banks (see the discussion of international lending below). Agents may be forced to herd in situations where market sentiment will dictate outcome—regardless of the underlying economics. What is an investor to do when the market sentiment is that the stock market will rise? The sentiment itself will cause the market to rise—an individual investor who, perhaps rightly, believes that a bubble is forming cannot expect to gain from this information unless the timing of the collapse of the bubble can be predicted. The rational strategy for this investor would be to herd.

In the public policy arena, public support for or opposition to particular policy measures frequently derives from what are called availability cascades. The more available information is, the more it is considered reliable. Public opposition to smoking is often cited as an example of herding caused by availability cascades.

Herd behavior may be rational behavior in the presence of external threats. Wild animals move together when threatened by a predator—in such cases, the optimal behavior for an individual member is to stay with the group. What is observed as herd behavior is really a consequence of individuals acting rationally.

Less rationally, social pressure may cause individuals to conform to what others are doing. Fads, manias, and fashions may be the consequences of herd behavior resulting from social pressure. Individuals may also seek to safeguard their personal reputation by following the crowd rather than risk the consequences of standing out. Adolescents’ behavior in high schools and conformity to politically correct language are examples of this latter type of herding.

INTERNATIONAL BANK LOANS AND INFORMATION CASCADES

International bank loans to developing countries from 1973 to 1982 provide a good illustration of how information cascades, managerial incentives, and moral hazard lead to herding. The oil price shocks of the 1970s left commercial banks from industrialized countries with large pools of recycled petrodollars and the developing countries with large current account deficits. Although the loan of excess bank liquidity to the developing countries would solve the imbalances for both groups at least temporarily, banks had limited knowledge regarding the credit risks of such loans. Some of the largest banks invested resources in developing the technology for risk assessment, but the large majority of the banks went along for the ride based
solely on their observation that the larger banks were willing to lend their own funds to developing countries and were lead-managing multibillion-dollar syndicates to provide funds to these borrowers. For the smaller banks, the marginal cost of doing their own analysis was much higher than the cost of gathering public information. The banks also felt pressure from the stock markets, which compared a bank’s earnings against those of others that were making what had become highly profitable loans (at least until the middle of 1982). The situation was not helped by the blessings given by the governments of Organisation for Economic Co-Operation and Development member states (who believed that recycled funds would support their exporters) and by international development organizations like the International Monetary Fund (which were unable to finance the developing countries’ deficits on their own). Such blessings were taken as an implicit understanding that these governments would help the banks should the banks’ lending behavior get them in trouble. Large commercial banks relied on an implicit protection inherent in their market power, believing that governments would not allow major banks to fail. Smaller banks may have herded for two reasons: (1) they could not replicate the information-gathering and analytic capabilities of the larger banks; and (2) they were sure that central banking authorities could not allow smaller banks to fail while saving the larger ones. Indeed all banks, large as well as small, were propped up after the Third World debt crisis began to unfold in August of 1982.

Herd behavior may be at least partly responsible for the Mexican crisis of 1994 and the East Asian crisis of 1997–1998. In both these situations, investment managers may have continued to invest in assets that had become excessively risky under the belief that markets would have penalized them if they failed to earn returns similar to their competitors.

Herd behavior, by encouraging overinvestment when things look good and mass exodus when that impression is reversed, adds to market volatility. It has, however, been difficult to develop tests that can establish either the presence or the impact of herding with some certainty. Future research in this field will have to focus on isolating real herding from mere similarity of outcomes.

**HEREDITY**

From a historical and biological perspective, heredity is the transfer of traits from a parent organism to its offspring. Traditional conceptualizations of heredity have focused on genes and the expression of genetic code that is transferred during reproduction. More recently and in response to knowledge about the limits of genetics in the human phenotypes and behavior, the conceptualization of heredity has been expanded to include the transfer of characteristics of the parent organism to offspring via a range of mechanisms, to include social institutions.

First described as animalcules and ultimately the basis of the school of scientists known as “spermists,” early thinkers such as Anton van Leeuwenhoek recognized that there were microscopic parts of the human existence. Others went further to suggest that sperm contained little men who were small representations of adults. As such, heredity was determined by the male of the species, and the role of women in reproduction was simply to carry the homunculus that had been deposited by the male. As a reflection of societal values and the diminished value of women, this theory of heredity prevailed throughout the seventeenth century.

In a controversial and radical move forward, Gregor Mendel was credited for determining the rules associated with genetic transfer in the 1800s in a series of experiments using garden peas. He established patterns of inheritance by observing frequency of traits such as seed color and based on assumptions that the frequency was a direct function of specified patterns of genetic transmission. It was he who observed patterns and coined subsequent rules of genetics, notably the basis of modern genomic theories.

During this era science recognized that both the male and female contributed to heredity and that the ovum and sperm fused toward the development of a synergistic being. The mechanism of this transmission was later determined to be deoxyribonucleic acid (DNA), which
was carried on chromosomes. From these seminal discoveries emerged the notion of the “central dogma” that indicates that DNA codes for ribonucleic acid (RNA) in transcription and RNA codes for proteins through a translational process. DNA was ultimately recognized as the blueprint in the direction of cellular activities, tissue and organ functions, and organismic activity and reproduction in both plants and animals.

The molecular structure of DNA was deduced in 1953 by James Watson and Francis Crick and has since served as the basis for understanding modern molecular and behavioral genetics. DNA is characterized as a polymeric double helix containing repeating nucleotide bases linked to phosphorylated sugars. These DNA molecules are arranged in linear or circular chromosomes, specific to species. In some organisms, chromosomes are circular and singular, but in most higher order organisms, chromosomes exist in linear and duplicate form. For example, humans have twenty-three pairs of chromosomes, where inheritance is derived from both mother and father. The sequence of repeating units that make up DNA determines the organism’s genotype and, ultimately, phenotype. Genetic variation occurs when there is a change in the DNA sequence secondary to biological or environmental provocation.

We have grown to recognize that heredity significantly influences how we look and how we behave, anticipate, and respond to our environmental context. This includes how and what we contract in terms of disease, how disease susceptibility is manifest in subsequent generations, and how wellness is defined. In a reciprocal fashion, our environmental context modifies the relationship between genotype and phenotype. Genotype influences phenotype but may produce several different phenotypes, depending on the environmental context. One example is phenylketonuria. This disease is caused by a genetic defect that results in a buildup of phenylalanine, which causes brain damage in children. However, if the affected child’s diet contains low levels of phenylalanine, mental retardation is prevented. This environmental change prevents disease presentation, even though the genotype would otherwise predict disease and mental retardation.

Inheritance in humans is often difficult to study. First, all study methods outside the laboratory are observational; scientific ethics prevent us from forcing or selectively controlling mating in humans. Secondly, it is very difficult to study human heredity prospectively because we have very long generation times. As a consequence, a number of techniques have been discovered that uniquely and creatively provide insight into the human inheritance. These include the use of pedigree, twin, and adoption studies. Pedigree studies give scientists a long-term picture of the inheritance of a given trait, or of several traits, by several generations of a given family. Specific rules regarding pedigrees allow researchers to determine the pattern of inheritance, such as whether a trait is autosomal dominant, autosomal recessive, X-linked dominant, X-linked recessive, or Y-linked. Dizygotic and monozygotic twins offer insight into the influence of environment on diseases with a significant genetic etiology. Since monozygotic twins share the same genetic makeup, it is expected that the manifestation of a genetic trait would be the same for the pair if they are in the same environment. Low concordance in monozygotic twins signals to investigators that environmental factors play a large role in the characteristic. Similarly, but from an environmental perspective, adoption studies also assist with determining the influence of environment and genetics on human functioning. Persons who are adopted often have few genes in common with their parents. However, they share the same environment for a number of years and often have health characteristics similar to those of their adoptive parents. Comparisons are made between adoptees and their adoptive parents, as well as between adoptees and one or both natural parents.

Inheritance is also of interest to those who study human behavior. For example, because of advances in statistical procedures and the use of twin methodologies in recent years, several researchers have begun evaluating the genetic influence of common psychiatric and personality traits, coping, and other behaviors. For example, using behavioral and molecular genetic analyses, Whitfield et al. (2006) recently reported that up to 35 percent of the variance in coping may be genetically mediated. This study suggests that genetics may provide a baseline for coping that is ultimately malleable and susceptible to learning and environmental influences. Similarly, Whitfield et al. (2007) reported that 60 percent of individual smoking behavior was genetically mediated, with very few meaningful differences in the genes that determine or influence smoking behavior between racially classified social groups.

Studies like those reported above have been used by some to promote biological explanations for social phenomena and suggest genetic predispositions for favorable or unfavorable social outcomes. Notably, the prevailing scientific evidence strongly challenges genetic explanations in the etiology of social outcomes and suggests that societal inequities are much more salient than are genetic factors.

The recent growth of genomics as a science has frequently exceeded our planning and thinking on topics such as ethics, morals, and the law. Our physical capacity to disentangle the building blocks of human existence has not always been equaled by our appreciation for the impact of such knowledge. For example, should predispo-
sitions identified by genetic testing be reported to insurance companies as an acceptable factor in the calculation of risk and an influence on the cost of insurance premiums? Should our ability to manipulate phenotypic characteristic in humans (blond hair, blue eyes, tall, etc.) be used in a fashion representative of a modern-day extension of the concept of eugenics put forth by Francis Galton in the mid-1800s? The eugenics movement advocated selective breeding for the purpose of producing desirable human phenotypes. Should parents be able to preselect the characteristics of their children prior to birth? We will likely continue to develop reactive ethics, morals, and laws as the result of advances in the genomic sciences. We view the future of the study of heredity to include a range of social, psychological, biological, and genetic influences. Genetics serves as a necessary but insufficient factor to understand the scope of intergenerational stability and variation.

HERMENEUTICS
Hermeneutics is a German word of Greek origin translated as interpretation in English. In the modern period it was originally used to refer to biblical interpretation and later to the general approach to literary and legal studies. In the past fifty years it has described an alternative to positivist approaches to the study of society. Positivist social science subscribes to methodological monism—the idea that there is a single scientific method, modeled after the natural sciences, that is the means for accumulating objective knowledge about the social and political world. As science, it looks to exclude normative and moral claims or evaluations about the social world. While acknowledging the importance of a scientific understanding of some aspects of the social world, hermeneutics rejects the methodological privilege that positivism ascribes to the natural sciences. Hermeneuticists argue that a more fundamental understanding and explanation of social life may be found in the meaning that action has for social and political actors. The emphasis on meaning implies that social behavior be construed as a text or text-analogue to be interpreted, according to Paul Ricoeur in Hermeneutics and the Human Sciences (1981), rather than as an object of scientific and technological understanding. In this respect hermeneuticists hold that the study of social life is more closely related to explanation and understanding of literary texts than to the objective study of physical objects or biological processes. Moreover, proponents argue that hermeneutics shows that the explanation of social life has a necessary moral or normative dimension to it.

Two of the earliest proponents of hermeneutics were Friedrich Schleiermacher (1768–1834) and Wilhelm Dilthey (1833–1911). Schleiermacher argued that the understanding of literary texts, legal documents, religious practices, or works of art require that one start with the object of interpretation and work backward to ascertain the intention of the author. Dilthey, building on Schleiermacher’s work, argued that historical events as well as works of art are the meaningful embodiment of the subjective intention of social actors and authors. Both thinkers, according to Hans-Georg Gadamer (1900–2000) in Truth and Method (1989), strove to develop an approach to interpretation that would uncover the objective meaning of the object of inquiry.

Schleiermacher and Dilthey formed the basis of what became known as the hermeneutics of recovery. The hermeneutics of recovery presupposes that the task of social inquiry is to capture the original intention or meaning that motivates and informs social action. This presupposes that there is an original, intended meaning that is determinate of social behavior and institutions. This version of hermeneutics often presupposes that empathy is a primary requirement for understanding social action and that explanations are to be couched in the subjective beliefs and intentions of actors.

A second approach, the hermeneutics of suspicion, is grounded in the work of Friedrich Nietzsche...
(1844–1900), Karl Marx (1818–1883), and Sigmund Freud (1856–1939), according to Ricoeur. It takes what proponents argue is a more critical approach to interpretation than found in the hermeneutics of recovery. The hermeneutics of suspicion maintains that the subjective intentions or conventional understanding of social actors is misleading and a distortion of social reality. Whether it is the conventional accounts of morality (Nietzsche), the ideology of the capitalist political economy (Marx), or the self-misunderstandings of individuals concerning the genuine motivations for their behavior and particularly their neuroses (Freud), the conscious, subjective, and prevailing understandings of society and social relations remain at the level of mere appearances and function to obscure and distort the reality that the social investigator needs to uncover to reveal the true meaning behind the apparent world.

More recently, two thinkers who have had the greatest impact on hermeneutics have been Martin Heidegger (1889–1976) and Ludwig Wittgenstein (1889–1951). Both Heidegger and Wittgenstein emphasize the priority of language for understanding human existence. For both, language is not just a tool that human beings possess. What is distinctive about human beings is that their experience of the world and their social relations are constituted by and expressed in language. Conversely, language gets its sense from the way of life (Wittgenstein) or the historical horizon (Heidegger) within which it evolves. Hence, there is a close connection between language and the social reality it helps to constitute and embody; the two are intertwined. The meaning of social action must be explained in terms of the linguistic tradition within which it is located, and the linguistic tradition in turn is explained by reference to the meaningful behavior of social actors. This to-and-fro movement of interpretation is what is meant by the hermeneutic circle.

Heidegger and Wittgenstein have influenced a wide range of interpretive social scientists (Hiley, Bohman, and Schusterman eds. 1991). Perhaps the two most important are Hans-Georg Gadamer (1989; see also Malpas, Arnswald, and Kertscher eds. 2002) and Charles Taylor (b. 1931) (1985, 1995), both of whom go beyond the hermeneutics of recovery and of suspicion. Building on Heidegger’s accounts of language and historicity, Gadamer argues that because human behavior and human understanding are historically and linguistically situated, a person’s understanding of the world is always both enabled and constrained by the person’s linguistic-historical tradition. This means that the prejudices or prejugements of that tradition are an inescapable and necessary part of people’s attempts to understand themselves as well as other historical traditions. This does not, however, mean that people are trapped in a prison of language. Rather, Gadamer argues that a dialogue with the other

encourages openness to the experience of other historical traditions. The result is a fusion of horizons that transcends previous understandings.

Taylor makes a similar point concerning language. Drawing on both Heidegger and Wittgenstein, he argues that language and the social practices in which it is embedded form a social imaginary that serves to express an understanding of the possibilities for human beings and for social and political life. Because that understanding is often inchoate, tacit, and imperfectly articulated, the goal of the social theorist is to give an expression to that social imaginary. Taylor ties this formulation of the self-understanding of social life to the possibility of deep forms of moral and political evaluation and reflection on the part of social and political actors (Taylor 1985a, 1985b, 1995). Moreover, building on the work of Gadamer, Taylor argues that Gadamer’s account of the fusion of horizons is pertinent not just for the understanding of other historical situations. It is also important in understanding other contemporary cultures and ways of life. The dialogical process that takes place in such efforts makes mutual understanding possible, though not guaranteed. Moreover, it makes greater reflective understanding of ourselves possible as well (Taylor in Malpas, Arnswald, and Kertscher 2002, 277–298).

The most recent significant development in hermeneutics is found in the work of Italian philosopher and social theorist Gianni Vattimo. In Beyond Interpretation: The Meaning of Hermeneutics for Philosophy (1997), Vattimo argues that taking the anti-essentialism of Nietzsche more seriously enables a more radical approach to hermeneutics and interpretation. He looks to challenge the distinction between the natural and the human sciences and to encourage a dialogue among science, art, religion, and ethics. Perhaps most important, along with Taylor he sees a more robust role for religion in the public sphere in what some hermeneuticists describe as a post-secular society.

CRITICISM OF HERMENEUTICS

Despite what proponents see as the promise of interpretive approaches to the study of social life, a number of criticisms have been offered of hermeneutics. One criticism continues to be advanced by conventional social scientists. Focusing on earlier forms of hermeneutics, they claim that empathic understanding may be a useful tool in formulating better hypotheses, but it does not exhaust the range of behavior that is of interest to social science. Moreover, it is not a criterion of verification in the research process, according to those committed to scientifically defined social inquiry.

A second criticism originates with critical theory and the work of Jürgen Habermas. In his debate with
Gadamer, Habermas argues that despite its importance for social inquiry, the hermeneutic emphasis on tradition, prejudices, and internal standards of rationality limits its critical leverage on prevailing ideologies that mask the social reality and specifically the exercise of power (Habermas 1987). Critical theorists maintain that this reflects an inherent, politically conservative bias.

A third criticism, from a perspective reminiscent of Michel Foucault (1926–1984), argues that hermeneutic/interpretive theory is still committed to conventional conceptions of truth and the self that are constituted by dominant discursive practices of the self and politics. These, in turn, deploy categories and practices of identity and difference that privilege some forms of human beings and understanding and marginalize or disqualify others. Hermeneutics fails to acknowledge the extent to which it is implicated in prevailing notions of the self and politics.

 Needless to say, interpretive theorists have responded to each of these criticisms. To the first they point out that the emphasis on language and its relation to social practice requires explanation that goes beyond empathic understanding. It involves the investigator in what the anthropologist Clifford Geertz (1987) calls depth interpretation. To the second and third criticisms, thinkers such as Gadamer and Taylor acknowledge the limitations of hermeneutics. Consequently, each argues that no historical prejudgments can be allowed to go unchallenged and that one needs to be aware of the ways that prevailing practices of politics and the self influence the possibilities of social explanation. What is perhaps most important, however, is not so much the specific responses of hermeneutics to its critics as the hermeneutic claim that because of the self-interpreting nature of human beings, social science is best understood as a form of practical reason analogous to Aristotle's fourth-century BCE discussion of practical wisdom in Book VI of the Nicomachean Ethics. This, according to Gibbons (2006), commits hermeneuticists to a dialogue with social actors and competing perspectives as the most promising response to theoretical contestation and pluralism.

HERNANDEZ V. TEXAS

Brown v. Board of Education was not, as almost everyone assumes, the first decision in which the U.S. Supreme Court, newly unified under the leadership of Chief Justice Earl Warren, set to dismantling Jim Crow segregation. That distinction belongs to a jury exclusion case decided two weeks earlier, Hernandez v. Texas. Hernandez is not just the first case in which the Warren Court took on segregation; it is also the greatest early triumph in the Mexican American struggle for civil rights and the first Supreme Court case to extend to Latinos constitutional protection against discrimination, no small matter now that Hispanics constitute the largest minority group in the United States.

After a two-day trial and less than three hours of deliberation, an all-white jury in Jackson County, Texas, in 1951, convicted Pete Hernández of murder and sentenced him to life in prison. The jury’s racial composition
was not an aberration for the era. The county stipulated at trial that no person with a Spanish surname had served on a trial or grand jury in more than a quarter century; more than 6,000 jurors had been seated, but in a county over 15 percent Mexican American, none had been from that group. The League of United Latin American Citizens (LULAC), then the most prominent Mexican American civil rights group in the country, agreed to help represent Hernández’s case before the Supreme Court.

A JIM CROW CASE
In deciding whether impermissible discrimination occurred, the Court considered a veritable catalog of Jim Crow oppressions. The Court noted that a restaurant in the county seat prominently displayed a sign saying “No Mexicans Served.” In addition, Jackson County residents routinely distinguished between “whites” and “Mexicans.” Business and civic groups almost entirely excluded Mexican American members. The schools were segregated, at least through the fourth grade, after which almost all Mexican Americans were forced out of school altogether. Finally, the opinion also recorded that on the Jackson County courthouse grounds there were two men’s bathrooms. One was unmarked. The other said “Colored Men” and “Hombres Aquí,” meaning, “Men Here.”

Consider more fully the underlying claim of jury exclusion. All-white juries imperiled Mexican American defendants who, such as Hernández, risked conviction by hostile and biased juries. Moreover, the Mexican American community suffered because white juries rarely and reluctantly convicted whites for depredations against Mexican Americans. Finally, determined opposition to jury exclusion arose because of its symbolism. In the context of Texas race politics, putting Mexican Americans on juries was tantamount to elevating such persons to equal status with whites. The idea that “Mexicans” might judge whites deeply violated Texas’s racial caste system. LULAC hoped Hernandez would help to topple a key pillar of Jim Crow: the belief that whites should judge all, but be judged by none but themselves.

FRUSTRATING A RACIAL ANALYSIS
Even though it challenged a Jim Crow practice, the Supreme Court did not decide Hernandez as a race case. The Court avoided a racial analysis because, strikingly, both parties argued that Mexican Americans were racially white.

As the evidence in Hernandez demonstrates, Anglos in Texas in the 1950s considered Mexicans an inferior race. This belief originated during the Anglo expansion into the Southwest in the early to mid-1800s that culminated in the expropriation of the northern half of Mexico. Initially, Mexicans in the United States, or at least the community’s leaders, resisted their racial subordination by constructing themselves as Mexican nationals and by envisioning an eventual return to Mexico. In the 1920s and 1930s, however, broad segments of the U.S. Mexican community came to see themselves as Americans. During this epoch Mexican community leaders embraced an assimilationist ideology; indeed, the label “Mexican American” emerges from this period and encapsulates the effort to both retain pride in the community’s Mexican cultural origins and to express an American national identity. Inseparable from this new assimilationist identity, however, was an engagement with American racial logic: on this score the community leaders argued that Mexican Americans were white.

These ideas found clear expression in LULAC’s arguments in Hernandez v. Texas. As in other cases, LULAC followed what it termed its “other white” legal strategy, protesting not segregation itself, but the inappropriate segregation of Mexican Americans as a white racial group. Thus, LULAC objected in its brief to the Supreme Court that, “while legally white,” in Jackson County “frequently the term white excludes the Mexicans and is reserved for the rest of the non-Negro population” (Brief of Petitioner at 38, Hernandez v. Texas, 347 U.S. 475, No. 406). Hernandez’s lawyers did not argue principally that segregation was legally wrong, but that Mexican Americans were legally white.

Meanwhile, Texas also adopted the claim that Mexican Americans were white—though to preserve segregation. LULAC and others had brought at least seven challenges to jury exclusion in Texas before Hernandez. In the initial cases Texas courts relied on testimony that Mexican Americans were “ignorant” or “not intelligent enough” in ruling that no Mexican Americans were qualified for jury service. By the late 1940s, however, the Texas courts shifted to a new approach. Seeking to turn LULAC’s arguments back against them, the courts began to hold that there was no discrimination because, like every jury member, Mexican Americans were white. As the decision under appeal in Hernandez reasoned, “Mexicans are white people…. The grand jury that indicted [Hernández] and the petit jury that tried him being composed of members of his race, it cannot be said … that appellant has been discriminated against in the organization of such juries” [Hernandez v. Texas, 251 S.W.2d 531, 536 (Tex. Crim. App. 1951)].

PROTECTING SUBORDINATED GROUPS
Confronted with contending parties who nevertheless agreed that Mexican Americans were white, the Supreme Court jettisoned an explicitly racial analysis. The case, Warren said, did not turn on “race or color.” However,
Herskovits, Melville J.

1895–1963

The American anthropologist Melville J. Herskovits spent his long academic career at Northwestern University, from 1927 until his death in 1963. There he established the first program in African studies at a major U.S. university. Herskovits has been regarded as a pioneer for advocating the serious and respectful study of Africa and the African diaspora. In The Myth of the Negro Past (1941), perhaps his best-known book, he sought to document the strength of an African cultural heritage of which blacks in the United States could be proud; he felt that once this was known and respected, antiblack prejudice would diminish.

Herskovits was born in Ohio to European-Jewish immigrant parents. Briefly a student at Hebrew Union College in Cincinnati, he enlisted in the U.S. army during World War I (1914–1918). He later attended Columbia University, where he studied with Franz Boas (1858–1942), who was seen as the “father” of American anthropology. Herskovits did a library doctoral dissertation on the “cattle complex” of East Africa with a focus on culture areas, tracing the diffusion of cultural traits. (The “cattle complex” referred to the cultural meanings, economic functions, and politics associated with cattle in East African cultures.) He then undertook physical anthropological research among African Americans. With his wife and anthropological partner Frances S. Herskovits (1897–1972), he did ethnographic fieldwork in Africa, in Dahomey (1931), and among Afro-American groups in Suriname (1928 and 1929), Haiti (1934), Trinidad (1939), and Brazil (1941–1942), before turning his attention more fully to African societies and politics.

Beginning with his popular and professional writings in the 1920s, Herskovits sought to combat racism and nativism through the use of anthropology conceived of as a science. He furthered Boas’s insistence on the plasticity of “race” by arguing that the “American Negro” was a racially mixed “amalgam” (Herskovits 1928, 1930). When he turned to the cultural anthropology of the African diaspora, Herskovits initially held that African Americans evinced “complete acculturation” to (white) U.S. mainstream culture (Jackson 1986). However, influenced by ethnologists and historians from Latin America and the Caribbean, African American intellectuals, and others, he soon redirected his scholarship to the study of what he called Africanisms, viewed as cultural elements of African provenance (Yelvington 2006). For Herskovits, in the acculturative context of African diaspora in the Americas, where culture contact occurred between African, European, Amerindian, and other cultures, Africanisms shaped the behavioral responses of what he called the “Negro in the New World,” and were even to be found among whites and other groups (e.g., in cuisine and speech in the U.S. South). Africanisms, which could sometimes be identified by African ethnic origin, were conceived as cultural baselines, and they were thought to vary in intensity across the region and across cultural forms such as kinship, language, dance, and games—indeed, they could be charted on a “scale of intensity”

...
continuum. They were found in folklore, but they were believed to be especially strong in religion (Baron 1994). In *Suriname Folk-Lore* (1936) the Herskovitse sought to demonstrate “correspondences” between Creole tales and tales of Old World origin; their work in *Dahomey* (Herskovits 1938a; Herskovits and Herskovits 1958) was concerned with the performance of narratives, creative expression, and the role of proverbs and riddles in enculturation, as well as with religion. In the 1930s Herskovits became interested in *acculturation*, or culture contact and culture change (Herskovits 1938b). In *Life in a Haitian Valley* (Herskovits 1937) he combined this interest with psychology, and introduced the idea of *socialized ambivalence* to describe what he saw as the conflict-ridden personalities that were the result of a dual cultural legacy. *Syncretism*, or the merging of two belief systems that still retain their identities, became important in Herskovits’s conceptual lexicon at this time. These concepts were brought together in *The Myth of the Negro Past* (1941). With *Trinidad Village* (Herskovits and Herskovits 1947), the concept of reinterpretation was used to designate how Afro-Americans retained “inner” behavior while giving new meaning to acquired cultural forms (Baron 2003). Herskovits’s promotion of cultural relativism and his mature ideas of cultural dynamics were elaborated most fully in *Man and His Works* (1948).

Herskovits was criticized by some such as Gunnar Myrdal (1898–1987), main author of the landmark *An American Dilemma* (1944), and African American sociologist E. Franklin Frazier (1894–1962) who, while joining with Herskovits’s goal of eliminating racism, could not agree with his theoretical stance.

Herskovits garnered an international reputation within the disciplines of anthropology and African diaspora studies, holding many positions of influence (Gershenhorn 2004) and publishing more than 400 books and scientific papers (Merriam 1964). Meanwhile, he trained a cadre of doctoral students at Northwestern University. His writings have inspired cultural and identity politics. All of which means that Herskovits’s work remains controversially relevant.

### HESSIAN MATRIX

The Hessian matrix was developed by Ludwig Otto Hesse (1811–1874), a German mathematician, though the term was first used by James Joseph Sylvester (1814–1897), an English mathematician who studied under Karl Gustav Jacob Jacobi (1804–1851). The Hessian is a square (the number of rows equal to the number of columns) and...
HETERARCHY

Complex systems science is the study of dynamic nonlinear systems that are not in equilibrium and do not act in a predictable manner. Key features (integration, communication, history/initial conditions) in complex biophysical systems correspond with key features of social systems: the holistic nature of culture, knowledge sharing through the senses, and the formative power of traditions, structures and materials, strategies, and habits of mind.

While several areas of complex systems research have potential for the social sciences, one of the most promising is the concept of heterarchy, which treats the diversity of relationships among system elements and offers a way to think about systemic change in spatial, temporal, and cognitive dimensions. Definitions of heterarchy are remarkably consistent across disciplines, while the work they do is extraordinarily diverse. The earliest definition describes the mind’s ability to hold conflicting values as a “heterarchy of values determined by the topology of nervous nets” (McCulloch 1945, p. 89). In artificial intelligence and computer design, the organization of computer sub-routines that can call one another is heterarchical (Minsky and Papert 1972, p. 2). A mathematician defines heterarchy as a program in which there is no highest level (Hofstadter 1979, p. 134). A sociologist who studies corporations defines heterarchy as “an emergent organizational form with distinctive network properties ... and multiple organizing principles” (Stark 2001, p. 71). A general purpose definition contrasts hierarchies, the elements of which are ranked relative to one another, with heterarchies, the elements of which are unranked, or possess the potential for being ranked in a number of differ-

symmetric (if the rows are written as the columns, the same matrix is produced) matrix whose entries are second-
order partial derivatives defined as $\frac{\partial^3 f}{\partial x_i \partial x_j \partial x_k}$. Since the Hessian is defined using second-order partial derivatives, the function must be continuous (smooth with no breaks or gaps) and differentiable (the derivative must exist at the point being evaluated).

The Hessian is used to characterize stationary or inflection points of a multivariable function, $f(x_i, x_j)$, as maximaums or minimaums. The identification as a maximum or minimum requires knowledge about the leading principal minor, $|H_k|$—the determinant of the principal submatrix of order $k$. For a stationary point to be a maximum, the leading principal minors must alternate in sign with $|H_1|$ being negative. If all the leading principal minors are positive, then the stationary point is a minimum. Failure to satisfy either of these conditions, which includes a leading principal minor of value zero, means characterization of the stationary point is inconclusive. The drawback of the Hessian is that calculating all the leading principal minors becomes laborious for an $n$-variable function with $n < 2$.

The Hessian, as defined, is used to characterize stationary points of unconstrained optimization problems, which are drawn from the theory of the firm. Goods are produced using capital ($K$) and labor ($L$) with the following production function, $f(L, K)$. Firms must decide the optimal combination to maximize profit. Applying the Hessian to such a problem generates a condition for profit maximization. For $|H_1|$ to be negative, the marginal product of labor must be diminishing—additional labor beyond the optimal choice decreases productivity, therefore, decreasing profit. The positive requirement of $|H_1|$ means that the marginal product of capital must also be diminishing. Without knowledge of these conditions, changes to the firm’s production policy would result in inefficient use of resources and a decrease in social welfare. Therefore, the Hessian matrix is an important tool in the policy analysis of unconstrained choices.

Heterarchy

(If the rows are written as the columns, the same matrix is produced) matrix whose entries are second-
order partial derivatives defined as $\frac{\partial^3 f}{\partial x_i \partial x_j \partial x_k}$.
Heterarchy does not stand apart from hierarchy; rather, the two forms are in a dialectical relationship. From a mathematical standpoint heterarchy is the more general category and subsumes hierarchy as a special case. The concept’s versatility permits its use as a physical structure, as an abstract model, or in an historical narrative. Heterarchy meets requirements for robust social theory inasmuch as the concept can relate the micro (individual) level to the macro (social) level, the agency of social actors to the social structure in which they operate, and provide an explanation for discontinuous and fundamental changes in the social system as a whole.

Heterarchy is a corrective to the naturalized characterization of power relations, which conflates hierarchy with order (Crumley 1987, 2005; Ehrenreich 1995). Since archaeology’s founding as a discipline, most interpretation has assumed a linear progression from small, early, “simple” societies to those that were more populous, later in time, and “complex.” Such a definition of complex (having more administrative levels) is in contrast to the definition of complexity in nonlinear systems (more richly networked). Political systems were assumed to have greater stability the more they tended toward tiered hierarchies of power. Yet powerful forces can manifest entirely outside the framework of state hierarchies and beyond their control. In non-linear systems, this is chaos or surprise, and reflects the characteristic brittleness of very hierarchical societies rendered vulnerable by systemic barriers to information transfer and limited recognition of other dimensions of power.

Archaeological and ethnographic evidence indicates that hierarchies and heterarchies of power coexist in all human societies, including states. Thus biological diversity has a correlate in human societies: the toleration of difference in individuals and groups offers a reserve of knowledge for use in problem solving, just as genetic and biological diversity increases ecosystem resilience. Similarly, organizational flexibility (economic, social, and political) enables societies to adjust to changed circumstances. As in ecology, researchers must remain aware of intensity, periodicity, and duration of relations; in human societies this might be thought of as the range of powers an individual, a group, or an institution has, and the regularity and duration of particular roles. Heterarchy is a fundamental principle of social organization.

HETERONORMATIVITY

Coined in 1991 by Michael Warner, a social critic, the term heteronormativity refers to pervasive and invisible norms of heterosexuality (sexual desire exclusively for the opposite sex) embedded as a normative principle in social institutions and theory; those who fall outside this standard are devalued. The concept is useful in attempting to understand the assumptions upon which heterosexuality rests, and in showing how and why deviations from heterosexual norms are subject to social and legal sanctions. For example, heteronormativity assumes a belief in dimorphic sexual difference (there are two sexes), biological essentialism (male and female functions are essentially different), and mimetic sex/gender relationship (psychosocial traits follow anatomy). Those who deviate from these assumptions of the gender binary by openly preferring romantic partners of the same sex, by changing from one sex to another, or by violating heterosexual norms in other ways, are marginalized. They are considered by many societies to be mentally defective and morally inferior, and they are subject to street violence, discrimination in employment, and withdrawal of social acceptance. These sanctions force conformity to sexual norms.

The term heteronormativity is itself controversial because it suggests to some a condemnation of those who espouse heterosexuality, or of those who oppose nonheterosexual behavior based on religious or moral beliefs. Some have suggested that it is used to enforce liberal orthodoxy. This is correct to some extent, in that the concept of heteronormativity focuses on the exclusivity of heterosexual norms. Thus, the concept implies criticism of those social conservatives who disapprove of nonheterosexual behavior. This criticism is justified to some degree because it is often difficult for those in the majority, heterosexual culture to realize the extent to which their culture routinely pervades society and constantly creates and enforces norms that marginalize nonheterosexual behavior. Normative heterosexual culture to realize the extent to which their culture routinely pervades society and constantly creates and enforces norms that marginalize nonheterosexual behavior. Normative heterosexual culture pressures all to conform, or at least to hide their differences, because those outside the norms are perceived as "strange." The normative culture also erases the extent to which it makes heterosexuality an issue. Because heterosexuality is the order of things, it seems as if nonheterosexuals make an issue of their sexuality, but heterosexuals do not. The gay American writer and radio host Michelangelo Signorile writes about the pervasiveness and invisibility of heterosexual norms:

These heterosexuals don’t realize that they routinely discuss aspects of their own sexuality every day: telling coworkers about a vacation they took with a lover; explaining to their bosses that they’re going through a rough divorce; bragging to friends about a new romance. Heterosexual reporters have no problem asking heterosexual public figures about their husbands, wives, girlfriends, boyfriends or children—and all these questions confirm and make an issue of heterosexuality. The ultimate example of making an issue of heterosexuality is the announcements in the newspapers every Sunday that heterosexuals are getting married. (Signorile 1993, xvii)

HETEROSKEDASTICITY

The classical statistical assumptions underlying econometric analysis refer to a set of requirements that need to hold in order for ordinary least squares (OLS) to yield the “best” estimator available for regression models. Heteroskedasticity violates the classical assumption that observations of the error term are drawn from a distribution that has a constant variance. Homoskedasticity, the assumption of constant variance for different observations of the error term, is not always realistic, because the larger an independent variable, the larger the variance of the associated disturbance.

In general heteroskedasticity is more likely to take place in cross-sectional models than in time-series models. However, heteroskedasticity can occur in time-series models with significant changes in the dependent variable. Heteroskedasticity can also occur in any model where the quality of data collection changes dramatically within the sample, or it can be caused by a model specification error.

When the violation of homoskedasticity takes place, ordinary least squares estimation of regression coefficient ($\beta^{OLS}$) remains unbiased, but it no longer has minimum variance among all linear unbiased estimators. Heteroskedasticity causes OLS to tend to underestimate the variances (and standard errors) of the coefficients. As a result, tests of statistical significances, such as the t-statistic and the F-statistic, cannot be relied on in face of uncorrected heteroskedasticity. In practice OLS usually turns up with higher t-scores than would be obtained if the error terms were homoskedastic, leading researchers to reject null hypotheses that should not be rejected.
There is no universally agreed-upon method of testing heteroskedasticity; econometric textbooks list as many as eight different methods for such testing. However, the visual inspection of residuals plotted against the suspected independent variable provide the first step for detecting the problem, and many computer packages can produce this graph. Some commonly used detection tests are the Goldfeld-Quandt test, the Glejser test, the Maximum Likelihood technique, the Park test, the White test, and the Bartlett's test. The majority of these tests use the residuals of an equation to test for the possibility of heteroskedasticity in the error terms. Certain disadvantages exist in every detection test, such as the computational cost (Maximum Likelihood technique) or the identification of a proper value for the best possible form of heteroskedasticity (Park test). It is worth mentioning, however, that an extensive Monte Carlo study of these techniques showed that the Maximum Likelihood approach is the most desirable.
